To a cuspidal automorphic representation of $\text{GSp}(4)$ over $\mathbb{Q}$, one can associate a compatible system of Galois representations $\{\rho_p\}_{p \text{ prime}}$. For $p$ sufficiently large, the deformation theory of the mod-$p$ reduction $\overline{\rho}_p$ is expected to be unobstructed – meaning the universal deformation ring is a power series ring. The global obstructions to deforming $\overline{\rho}_p$ is controlled by certain adjoint Bloch-Kato Selmer groups, which are expected to be trivial for $p$ large enough.

I will talk about some recent results showing that there are no local obstructions to the deformation theory of $\overline{\rho}_p$ for almost all $p$.

This is joint work with M. Broshi, C. Sorensen, and T. Weston.
