DIAGONAL ACTIONS IN POSITIVE CHARACTERISTIC

M. EINSIEDLER, E. LINDENSTRAUSS, AND A. MOHAMMADI

Abstract. We prove positive characteristic analogues of certain measure rigidity theorems in characteristic zero. More specifically we give a classification result for positive entropy measures on quotients of $\text{SL}_d$ and a classification of joinings for higher rank actions on simply connected absolutely almost simple groups.

1. Introduction

Let $G$ be a locally compact, second countable group and let $\Gamma$ be a lattice in $G$. Put $X = G/\Gamma$. A subset $S \subset X$ is called homogeneous if there exists a closed subgroup $\Sigma < G$ and some $x \in X$ such that $\Sigma x$ is closed and supports a $\Sigma$-invariant probability measure. A probability measure $\mu$ on $X$ is called homogeneous if $\text{supp} \mu$ is homogeneous and $\mu$ is the $\Sigma$-invariant probability measure on $\text{supp} \mu$.

Let $A$ be a closed abelian subgroup of $G$. An $A$-invariant probability measure $\mu$ on $G/\Gamma$ will be called almost homogeneous if

$$\mu = \int_{A/A \cap \Sigma} a \ast \nu \, da$$

where

1. $\Sigma \subset G$ is a closed subgroup such that $A/A \cap \Sigma$ is compact,
2. $\nu$ is a homogeneous measure stabilized by $\Sigma$,
3. $da$ is the Haar probability measure on the group $A/A \cap \Sigma$.

Let $K$ be a global function field, i.e. a finite extension of the field of rational functions in one variable over a finite field $\mathbb{F}_q$. For any place $w$ of $K$ we let $K_w$ denote the completion of $K$ at $w$, and let $\mathfrak{o}_w$ be the ring of integers in $K_w$. As in the case of number fields, the field $K$ embeds diagonally in the restricted product $\prod_w K_w$. Given a place $v$ we put

$$\mathfrak{O}_v = K \cap \prod_{w \neq v} \mathfrak{o}_w$$

to be the ring of $v$-integers in $K$.

For the rest of this paper we will assume that a place $v$ of $K$ is fixed and put

$$k := K_v, \quad \mathfrak{o} := \mathfrak{o}_v, \quad \mathfrak{O} := \mathfrak{O}_v.$$

Recall that we may and will identify $k$ with $\mathbb{F}_q((\theta^{-1}))$, the field of Laurent series over the finite field $\mathbb{F}_q$, after this identification we have $\mathfrak{o} = \mathbb{F}_q[[\theta^{-1}]]$, [35, Ch. 1].

M.E. acknowledges support by the SNF (Grant 200021-152819).
E.L. acknowledges the support of the ERC (AdG Grant 267259).
A.M. was supported in part by NSF (DMS #1500677, #1128155, and #1724316) and Alfred P. Sloan Research Fellowship.
The most familiar case is when $K = \mathbb{F}_q(\theta)$, the field rational functions in one variable with coefficients in $\mathbb{F}_q$. Then if we choose the valuation $v$ coming from $\theta^{-1}$ we have $\mathcal{O}_v = \mathbb{F}_q[\theta]$ is the polynomial ring.

1.1. **Positive entropy classification for measures on quotients of $SL_d$.** Let $G = SL(d, k)$ and $\Gamma = \text{SL}(d, \mathcal{O})$. Then $\Gamma$ is a lattice in $G$ and we let $X := G/\Gamma$. Furthermore, we let $A$ be the full diagonal subgroup of $\text{SL}(d, k)$. **Throughout the paper we always assume $d > 2$.**

Given an $A$-invariant probability measure $\mu$ we let $h_\mu(a)$ denote the measure theoretic entropy of $a \in A$.

**Theorem 1.1.** Suppose $\mu$ is an $A$-invariant ergodic probability measure on $X$, further assume that $h_\mu(a) > 0$ for some $a \in A$. Then $\mu$ is almost homogeneous.

We note that this is a positive characteristic analogue of the result of [10] by A. Katok with the two first named authors.

The conclusion of Theorem 1.1 cannot be strengthened to saying that $\mu$ is homogeneous. In fact, $K = \mathbb{F}_q(\theta)$ has many subfields $K'$ (without a bound on $[K : K']$), defining $K'$ to be the closure of $K'$ in $k$, one could take the measure $\nu$ to be the Haar measure on the closed orbit $\Sigma \Gamma$ for $\Sigma = \text{SL}(d, k')$, and $\mu$ could be as in (1.1) since $A/(A \cap \Sigma)$ is compact.

1.2. **Joining classification.** Furstenberg [18] introduced the following notion in 1967 that has since become a central tool in ergodic theory. Suppose we are given two measure preserving systems for a group $S$ acting on Borel probability spaces $(X_i, m_i)$ for $i = 1, 2$. A joining is a Borel probability measure $\mu$ on $X_1 \times X_2$ such that the push-forwards satisfy $(\pi_i)_* \mu = m_i$ for $i = 1, 2$ and is invariant under the diagonal action on $X_1 \times X_2$, i.e. $s.(x_1, x_2) = (s.x_1, s.x_2)$ for all $s \in S$ and $(x_1, x_2) \in X_1 \times X_2$.

We give a classification of ergodic joinings in the following setting. Let $G_i$ be connected, simply connected, absolutely almost simple groups defined over $k$ for $i = 1, 2$. Put $G_i = G_i(k)$ and let $\Gamma_i$ be a lattice in $G_i$ and define $X_i = G_i/\Gamma_i$ for $i = 1, 2$. Denote by $m_i$ the Haar measure on $X_i$.

Let $\lambda_i : G_m^2 \to G_i$ be two algebraic monomorphisms defined over $k$, and put $A_i = \lambda_i(G_m^2)$. We define the notion of joining as above using these monomorphisms.

Let $A = \{(\lambda_1(t), \lambda_2(t)) : t \in G_m^2\}$ and let $A = A(k)$.

**Theorem 1.2.** Assume $\text{char}(k) \neq 2, 3$. Suppose that $G_i, A_i$, and $X_i$ are as above for $i = 1, 2$. Let $\mu$ be an ergodic joining of the action of $A_i$ on $(X_i, m_i)$ for $i = 1, 2$. Then $\mu$ is an algebraic joining. That is, one of the following holds

1. $\mu = m_1 \times m_2$ is the trivial joining, or
2. $\mu$ is almost homogeneous, moreover, the group $\Sigma$ appearing in the definition of a almost homogeneous measure satisfies the following
   - $\pi_i(\Sigma) = G_i$ for $i = 1, 2$, and
   - $\ker(\pi_i|_{\Sigma})$ is contained in the finite group $Z(G_1 \times G_2)$ for $i = 1, 2$.

These results are a positive characteristic analogue of the work [12] (see also [11] for stronger results in the zero characteristic setting) of the two first named authors.

It is also worth mentioning that even for joinings, in general, virtual homogeneity can not be improved to homogeneity. Indeed, let $k/k'$ be a Galois extension of
degree 2 with the nontrivial Galois automorphism \( \tau \). Let \( G_1 = G_2 = \text{SL}_3 \) and let \( \Gamma_1 = \Gamma \) and \( \Gamma_2 = \tau(\Gamma) \) for a lattice \( \Gamma \subset \text{SL}(3, k) \). Let \( \lambda_1 = \lambda_2 \) be the monomorphism \((t, s) \mapsto \text{diag}(t, s, (ts)^{-1})\). The measure \( \nu \) could be the Haar measure on the closed orbit \( \Sigma(\Gamma_1 \times \Gamma_2) \) of \( \Sigma = \{(g, \tau(g)) : g \in \text{SL}(3, k)\} \) and \( \mu \) could be as in (1.1).

1.3. **Main difference to the zero characteristic setting.** We apply in this paper the high entropy method that was developed in the zero characteristic setting in a series of papers, see [8, 10, 9, 14], and for Theorem 1.1 also the low entropy method, see [24, 10, 13]. These arguments use crucially leaf-wise measures for the root subgroups (or more generally the coarse Lyapunov subgroups), which are locally finite measures on unipotent subgroups.

Suppose we are able using the above tools to show the leafwise measures on the coarse Lyapunov subgroups have some invariance. Then using Poincaré recurrence along \( A \) one can show the invariance group has arbitrarily large and arbitrarily small elements. The key difference lies in the next step of the argument. In the zero characteristic setting a closed subgroup of a unipotent group containing arbitrarily small and arbitrarily large elements has to contain a one-parameter subgroup – and hence the leafwise measures for the one-parameter subgroup have to be Haar which gives unipotent invariance for the measure under consideration.

In the positive characteristic world this is very far from being true. In fact using a fairly direct adaptation of the methods used in [10, 12] etc. one can find almost surely an unbounded subgroup of a unipotent group that has positive Hausdorff dimension which again preserves the leafwise measure. However, as there are uncountably many such subgroups and since these may vary from one point to another it is not clear how to continue from this by purely dynamical methods.

Decomposing the measure \( \mu \) according to the Pinsker \( \sigma \)-algebra \( \mathcal{P}_a \) (for some \( a \in A \)) we find a subgroup of \( G \) that preserves the conditional measure on an atom for \( \mathcal{P}_a \) and has a semisimple Zariski closure. To classify such subgroups we use a result of Pink [28] (see also [22] for related results by Larsen and Pink). This allows us to deduce invariance under the group of points of a semisimple subgroup for some local subfield. After this we use a measure classification result [27] by Alireza Salehi-Golsefidy and the third named author (as a replacement of Ratner’s measure classification theorem [30, 31] extended to the \( S \)-arithmetic setting by Ratner [31] resp. Margulis and Tomanov [26]).

We note that analogues of the measure rigidity theorems of Ratner for general unipotent flows in positive characteristic setting are not yet known. Some special cases have been investigated, specifically the above mentioned paper [27] which is used in our proof and the earlier paper [7].

**Acknowledgements.** The authors would like to thank Alireza Salehi-Golsefidy, Michael Larsen, Gopal Prasad, and Richard Pink for helpful conversations. The results of [27] are used in our work in an essential way, and we thank Alireza for agreeing to present the results in that paper in a way that would be convenient for our purposes.

2. **Notation**

2.1. Throughout, \( K \) denotes a global function field. We let \( v \) be a place in \( K \), fixed once and for all. Denote by \( \mathcal{O} \) the ring of \( v \)-integers in \( K \). Put \( k := K_v \) the completion of \( K \) at \( v \). Then \( k \) is identified with \( \mathbb{F}_q((\theta^{-1})) \), the field of Laurent series
over the finite field $\mathbb{F}_q$ where $q$ is a power of the prime number $p = \text{char}(K)$. We denote by $\mathfrak{o}$ the ring of integers in $k$. Then $\mathfrak{o} = \mathbb{F}_q[[\theta^{-1}]]$ and the maximal ideal $\mathfrak{m}$ in $\mathfrak{o}$ equals $\theta^{-1}\mathfrak{o}$. The norm on $k$ will be denoted by $| \cdot |_v$, or simply by $| \cdot |$; note that with our notation we have $|\theta|_v > 1$. With our normalizations $\log_q(|r|)$ is the $v$-valuation of $r \in k$.

Unless explicitly mentioned otherwise, a subfield $k' \subset k$ is always an infinite and closed subfield of $k$; hence, $k/k'$ is a finite extension.

2.2. Let $G$ be a connected, simply connected, semisimple $k$-algebraic group. Put $G = G(k)$. We always assume $G$ is $k$-isotropic.

Fix a maximal $k$-split $k$-torus $S$ of $G$. We will always assume $A$ is contained in $S$ in the case of Theorem 1.1 and similarly $A_i$ are contained in $S_i$, for $i = 1, 2$, in the case of Theorem 1.2.

Let $\Phi$ denote the set of relative roots $\Phi(S, G)$; this is a (possibly not reduced) root system, see [2, Thm. 21.6]. Let $\Phi^\pm$ denote positive and negative roots with respect to a fixed ordering on $\Phi$.

Recall from [2, Remark 2.17, Prop. 21.9, and Thm. 21.20] that for any $\alpha \in \Phi$, there exists a unique affine $k$-split unipotent $k$-subgroup $U(\alpha)$ which is normalized by $Z_G(S)$, the centralizer of $S$, and its Lie algebra is $g(\alpha) := g_\alpha + g_{2\alpha}$. Here, as usual, for a root $\beta \in k\Phi$ we let $g_\beta$ be the subspace in the Lie algebra on which $S$ acts by the root $\beta$.

A subset $\Psi \subset k\Phi$ is said to be closed if $\alpha \in \Psi$ and $\frac{1}{2} \alpha \in \Phi$ implies $\frac{1}{2} \alpha \in \Psi$, and $\alpha, \beta \in \Psi$ with $\alpha + \beta \in k\Phi$ implies $\alpha + \beta \in \Psi$. A subset $\Psi \subset k\Phi$ is said to be positively closed if it is closed and is contained in $k\Phi^+$ for some ordering of the root system. For any positively closed subset $\Psi \subset k\Phi$ there exists a unique affine $k$-split unipotent $k$-subgroup $U_\Psi$ which is normalized by $Z_G(S)$ and its Lie algebra is the sum of $\{g(\alpha) : \alpha \in \Psi\}$. Moreover, $U_\Psi$ is generated by $\{U(\alpha) : \alpha \in \Psi \setminus 2\Psi\}$, i.e., $U_\Psi$ is $k$-isomorphic as a $k$-variety to $\prod_{\alpha \in \Psi \setminus 2\Psi} U(\alpha)$ where the product can be taken in any order, [2, Prop. 21.9 and Thm. 21.20].

If $\Psi = \{\alpha\}$ and no multiple of $\alpha$ is a root, we simply write $U_\alpha$ for $U_\Psi$. We put $U_\psi = U_\psi(k)$ for $\psi = \alpha$, $(\alpha) = R_+ \alpha \cap k\Phi$, and $\Psi$.

Given a subset $E \subset G$ we let $\langle E \rangle$ denote the closed (in the Hausdorff topology) group generated by $E$.

For each $\alpha \in k\Phi$ we fix a collection of one parameter subgroups, $\{u_{\alpha,i} : 1 \leq i \leq d_\alpha\}$ generating $U(\alpha)$ and define $U(\alpha)[R]$ to be the compact group generated by $\{u_{\alpha,i}(r) : |r|_v < R, 1 \leq i \leq d_\alpha\}$. For any positively closed $\Psi \subset \Phi$ we put

$$U_\Psi[R] = \{\{U(\alpha)[R] : (\alpha) \subset \Psi\}$$

Given $a \in A$ we put

$$(2.1) \quad W^+_G(a) = \{g \in G : \lim_{k \to \pm \infty} a^{-k}ga^k = \text{id}\}$$

to be the expanding (resp. contracting) horospherical subgroup corresponding to $a$.

2.3. Let $\Phi(A, G)$ denote the set of roots of $A$, i.e., the characters for the adjoint action of $A$ on the Lie algebra of $G$. We will say $\Psi \subset \Phi(A, G)$ is positively closed if

$$\{\alpha \in \Phi(S, G) : \alpha | A \in \Psi\}$$
is positively closed in the sense of §2.2 and set

$$V_\Psi := \prod_{\alpha | A \in \Psi} U(\alpha)$$

for any positively closed subset $\Psi \subset k\Phi(A, G)$. We also let $V_\Psi$ denote the underlying algebraic group. An important special case is when $\Psi = [\alpha] = \{r\alpha \in k\Phi(A, G) : r > 0\}$ for some $\alpha \in k\Phi(A, G)$. In this case $V[\alpha]$ is called a coarse Lyapunov subgroup.

3. Preliminary results

3.1. Algebraic structure of compact subgroups of semisimple groups.

Given a variety $M$ which is defined over $k$ there are two topologies on $M(k)$, namely, the Zariski topology and the topology arising from the local field $k$. We will refer to the latter as the Hausdorff topology.

The following theorems are very special cases of the work of Pink, [28], and will play an important role in our study. Roughly speaking, they assert that compact and Zariski dense subgroups of semisimple groups have an algebraic description.

**Theorem A.1** (Cf. [28], Theorems 0.2 and 7.2) Suppose $Q \subset \text{SL}(2, k)$ is a compact and Zariski dense subgroup. Further, assume that

(3.1) $$Q = \{g \in Q : g \text{ is a unipotent element}\}$$

Let $k''$ be the closed field of quotients generated by $\{\text{tr}(\rho(g)) : g \in Q\}$, where $\rho$ is the unique irreducible subquotient of the adjoint representation of $\text{PGL}_2$, and set

(3.2) $$k' := \begin{cases} k'' & \text{if } \text{char}(k) \neq 2, \\ \{c : c^2 \in k''\} & \text{if } \text{char}(k) = 2. \end{cases}$$

Then, there is a $k$-isomorphism (unique up to unique isomorphism)

$$\varphi : \text{SL}_2 \times_{k'} k \to \text{SL}_2$$

so that $Q$ is an open subgroup of $\varphi(\text{SL}(2, k'))$.

**Proof.** Denote by $\bar{Q}$ the image of $Q$ under the natural map from $\text{SL}_2$ to $\text{PGL}_2$. Then $\bar{Q}$ is Zariski dense in $\text{PGL}_2$.

By [28] Thm. 0.2, there exist

- a subfield $k' \subset k$,
- an absolutely simple adjoint group $L$ defined over $k'$, and
- a $k$-isogeny $\phi : L \times_{k'} k \to \text{PGL}_2$ whose derivative vanishes nowhere,

where $k'$ is unique, and $L$ and $\phi$ are unique up to unique isomorphism, so that the following hold.

- $\bar{Q} \subset \varphi(L(k'))$, see [28] Thm. 3.6,
- let $\tilde{L}$ denote the simply connected cover of $L$ and let $\tilde{\phi}$ be the induced isogeny from $\tilde{L} \times_{k'} k$ to $\text{SL}_2$. Then any compact subgroup $Q' \subset \tilde{\phi}(\tilde{L}(k'))$ which is Zariski dense and normalized by $[\bar{Q}, \bar{Q}]$ is an open subgroup of $\tilde{\phi}(\tilde{L}(k'))$, see [28] Thm. 7.2.

The fact that $k'$ can be taken as in (3.2) follows from the proof of [28] Prop. 0.6(a)], see in particular [28] Prop. 3.14.
Moreover, [28, Prop. 1.6] implies that there are no non-standard isogenies for groups of type $A_1$. Hence, by [28, Thm. 1.7(b)], the isogeny $\phi$ above is an isomorphism.

We now prove the other claims. First let us recall from [19] Thm. 2 that since $\text{SL}_2$ is simply connected, for every unipotent element $u \in \text{SL}(2, k)$ there exists a parabolic $k$-subgroup, $P$, of $\text{SL}_2$ so that $u \in R_u(P(k))$. Hence, (3.3) implies that
\begin{equation}
Q = \langle Q \cap R_u(P) : P \text{ is a parabolic subgroup of } \text{SL}(2, k) \rangle.
\end{equation}

Let $P$ be a parabolic subgroup so that $Q \cap R_u(P) \neq \{1\}$. Let $a$ be a diagonalizable matrix in $\text{PSL}(2, k) \subset \text{PGL}(2, k)$ whose conjugation action contracts $R_u(P)$. Then $a$ contracts $\phi(h)$ for any $h \in \mathcal{L}(k')$, where $\phi(h) \in R_u(P)$. Put $a' = \phi^{-1}(a)$, the above implies that $h$ can be contracted to identity using conjugation by $a'$. In particular, $h$ is a unipotent element.

In view of (3.1) and the above discussion $\overline{\mathcal{L}}(k')$ contains nontrivial unipotent elements. Thus we get from [1, Cor. 3.8], see also [19], that $\overline{\mathcal{L}}$ is $k'$-isotropic. Since $\mathcal{L}$ is simply connected, and $\phi$ is an isomorphism we get $\mathcal{L} = \text{SL}_2$.

Finally, using [25, Ch. I, Thm. 2.3.1], we have
\begin{equation}
Q \cap R_u(P) \subset \overline{\phi(\mathcal{L}(k'))}
\end{equation}
for any parabolic subgroup $P$ of $\text{SL}(2, k)$. Hence $Q \subset \overline{\phi(\mathcal{L}(k'))}$ by (3.3). This finishes the proof in case (a).

For the second theorem we need some more terminology. By a linear algebraic group $G$ over $k \oplus k$ we mean $G_1 \coprod G_2$ where each $G_i$ is a linear algebraic group over $k$. The adjoint representation of $G$ on $\text{Lie}(G) = \text{Lie}(G_1) \oplus \text{Lie}(G_2)$ is the direct sum of the adjoint representations of $G_i$ on $\text{Lie}(G_i)$, and the group of $k \oplus k$-points of $G$ is $G(k \oplus k) = G_1(k) \times G_2(k)$.

Suppose $G = G_1 \coprod G_2$ is a fiberwise absolutely almost simple, connected, simply connected $k \oplus k$-group. Let $\rho = (\rho_1, \rho_2)$ where $\rho_i$ is the unique irreducible quotient of the adjoint representation of $G_i^{ad}$, see [28 §1]. The trace $\text{tr}(\rho(g))$ for an element $g = (g_1, g_2)$ in $G(k \oplus k)$ is defined by
\[ \text{tr}(\rho(g)) = (\text{tr}(\rho_1(g_1)), \text{tr}(\rho_2(g_2))) \in k \oplus k. \]

Given a subfield $k' \subset k$ and a continuous embedding $\tau : k' \to k$ of fields, we put
\begin{equation}
\Delta_{\tau}(k') = \{(c, \tau(c)) : c \in k'\}.
\end{equation}
As in [28, pp. 16–17], by a semisimple subring $k'' \subset k \oplus k$ we mean one of the following
1. $k'' = k_1 \oplus k_2$ where $k_i \subset k$ is a closed subfield for $i = 1, 2$,
2. $k'' = \Delta_{\tau}(k')$ for a subfield $k' \subset k$ and a continuous embedding $\tau : k' \to k$.

If $k'' = \Delta_{\tau}(k')$ and $H$ is a $k'$-group, we write, by abuse of notation, also $H$ for the corresponding $\tau(k')$-group as well as the $\Delta_{\tau}(k')$-group obtained from $H$. The base change of $H$ from $\Delta_{\tau}(k)$ to $k \oplus k$ is then defined by
\[ H \times_{\Delta_{\tau}(k')} (k \oplus k) = \left( H \times_{k'} k \right) \coprod \left( H \times_{\tau(k')} k \right). \]

**Theorem A.2** (Cf. [28], Theorems 0.2 and 7.2). Assume that $\text{char}(k) \neq 2, 3$, and let $G_i, i = 1, 2$ be absolutely almost simple, connected, simply connected $k$-groups.
Let $Q \subset G_1(k) \times G_2(k)$ be a compact subgroup so that $\pi_i(Q)$ is Zariski dense in $G_i$ for $i = 1, 2$. Further, assume that

$$Q = \{g \in Q : g \text{ is a unipotent element}\},$$

Let $k'' \subset k \oplus k$ be defined as follows.

$$k'':= \text{the closed ring of quotients generated by } \{\text{tr}(\rho(g)) : g \in Q\}.$$

Then one of the following holds.

1. There are
   - (i) closed subfields $k_i \subset k$ so that $k'' = k_1 \oplus k_2$,
   - (ii) $k_i$-groups $H_i$, and
   - (iii) $k$-isomorphism $\varphi_i : H_i \times_k k \to G_i$,
   so that $Q$ contains an open subgroup of the form
     $$Q_1 \times Q_2 \subset \varphi_1(H_1(k_1)) \times \varphi_2(H_2(k_2)).$$

2. There are
   - (i') a closed subfield $k' \subset k$ and a continuous embedding $\tau : k' \to k$ so that $k'' = \Delta_{\tau}(k')$,
   - (ii') a $k'$-group $H$, and
   - (iii') a $k \oplus k'$-isomorphism $\varphi : H \times_{k'} (k \oplus k) \to G_1 \sqcup G_2$,
   so that $Q$ is an open subgroup of $\varphi(H(k'))$.

Moreover, $k''$ is unique, and $H$ and $\varphi$ are unique up to unique isomorphisms.

Proof. Similar to Theorem A.1 these assertions are special cases of results in [28] as we now explicate. Let $G_i^{ad}$ denote the adjoint form of $G_i$ for $i = 1, 2$. Denote by $\bar{Q}$ the image of $Q$ under the natural map from $G_1 \sqcup G_2$ to $G_1^{ad} \sqcup G_2^{ad}$. Then $\pi_i(\bar{Q})$ is Zariski dense in $G_i^{ad}$ for $i = 1, 2$.

By [28] Thm. 0.2] we have the following. There exist

- a semisimple subring $k'' \subset k \oplus k$,
- a fiberwise absolutely simple adjoint group $L$ defined over $k''$, and
- a $k \oplus k$-isogeny $\phi : L \times_{k''} (k \oplus k) \to G_1 \sqcup G_2$ whose derivative vanishes nowhere,

where $k''$ is unique, and $L$ and $\phi$ are unique up to unique isomorphism, so that the following hold.

- $Q \subset \phi(L(k''))$, see [28] Thm. 3.6],
- let $\tilde{L}$ denote the simply connected cover of $L$ and let $\tilde{\phi}$ be the induced isogeny from $\tilde{L} \times_{k''} (k \oplus k)$ to $G_1 \sqcup G_2$. Then any compact subgroup $Q' \subset \tilde{\phi}(\tilde{L}(k''))$ which is fiberwise Zariski dense and normalized by $[\bar{Q}, \bar{Q}]$ is an open subgroup of $\tilde{\phi}(\tilde{L}(k''))$, see [28] Thm. 7.2].

Recall our assumption that $\text{char}(k) \neq 2, 3$. Therefore, $G_1$ and $G_2$ have no non-standard isogenies, see [28] Prop. 1.6]. This also implies that $k''$ can be taken as in (3.6], see [28] Prop. 3.13 and Prop. 3.14]. Moreover, by [28] Thm. 1.7(b)], the isogeny $\phi$ above is an isomorphism.

The above discussion thus implies that if $k'' = \Delta_{\tau}(k')$, see (k''-2), then (i'), (ii'), and (iii') hold. Similarly, if $k'' = k_1 \oplus k_2$, see (k''-1), then (i), (ii), and (iii) hold, in view of the above discussion, and the description of algebraic groups and their isogenies over $k_1 \oplus k_2$ and $k \oplus k$. 
Finally recall from (3.5) that $Q$ is generated by unipotent elements, therefore, $Q \subset \tilde{\phi}(L(k^\prime))$, see [25] Ch. I, Thm. 2.3.1. This finishes the proof of case (b). 

We will also need the following lemma. Let $U^+$ (resp. $U^-$) denote the group of upper (resp. lower) triangular unipotent matrices in $SL_2$. Also let $T$ denote the group of diagonal matrices in $SL_2$. Put $U^\pm := U^\pm(k)$ and $T := T(k)$.

Lemma 3.1. Let the notation be as in Theorem A.1. Put $E = \varphi(SL(2,k'))$, then

1. $E = (E \cap U^+, E \cap U^-)$.
2. $E \cap T$ is unbounded.

Proof. We showed in the course of the proof of Theorem A.1 that there are nontrivial unipotent elements $h^\pm \in SL(2,k')$ so that $\varphi(h^\pm) \in U^\pm$, respectively. Since $SL_2$ is simply connected, it follows from [19] Thm. 2 that there are $k'$-parabolic subgroups $P^\pm$ of $SL_2$ so that $h^\pm \in R_u(P^\pm)$. The groups $R_u(P^\pm)$ are one dimensional $k'$-split unipotent subgroups, hence $\varphi(R_u(P^\pm)(k')) \subset \varphi(SL_2)$ is an infinite group. Note that $\varphi(SL_2) = SL_2$ in Theorem A.1. Let $U^\pm_k$ denote the Zariski closure of $\varphi(R_u(P^\pm)(k'))$. Then $U^\pm_k$ is a nontrivial connected unipotent subgroup of $\varphi(SL_2)$ which intersects $U^\pm \cap \varphi(SL_2)$ nontrivially. Therefore, $U^\pm_k = U^\pm \cap \varphi(SL_2)$ which implies

\[ \varphi(R_u(P^\pm)(k')) \subset U^\pm \cap E. \]

Using the fact that $SL_2$ is simply connected one more time, we note that $SL(2,k')$ is generated by $R_u(P^\pm)(k')$, [25] Ch. 1, Thm. 2.3.1. This and (3.7) imply (1) in the lemma.

We now show (2) in the lemma. Let $S = P^+ \cap P^-$. Then $S$ is a one dimensional $k'$-split $k'$-torus; put $S = S(k')$. Now

\[ T' := \varphi(S) \subset TU^+ \cap TU^- = T \]

satisfies the claim in (2). 

3.2. Measures invariant under semisimple groups. We will state in this subsection the measure classification result by Salehi-Golsefidy and the third named author [27] for probability measures that are invariant under non-compact semisimple groups in the positive characteristic setting.

For this we need some notation and definitions, these generalize the notions defined in (2.1) to a general connected group. Let $k$ be a local field. Suppose $M$ is a connected $k$-algebraic group, and let $\lambda : G_m \to M$ be a non-central homomorphism defined over $k$. Define $-\lambda(\cdot) = \lambda(\cdot)^{-1}$. As in [29] §13.4 and [6] Ch. 2 and App. C, we let $P_M(\lambda)$ denote the closed subgroup of $M$ formed by those elements $x \in M$, such that the map $r \in G_m \mapsto \lambda(r)x\lambda(r)^{-1} \in M$ extends to a map from $G_a$ into $M$.

Let $W^+_M(\lambda)$ be the normal subgroup of $P_M(\lambda)$, formed by $x \in P_M(\lambda)$ such that $\lambda(r)x\lambda(r)^{-1} \in e$ as $r$ goes to $0$. The centralizer of the image of $\lambda$ is denoted by $Z_M(\lambda)$. Similarly define $W^-_M(-\lambda)$ which we will denote by $W^-_M(\lambda)$.

The multiplicative group $G_m$ acts on $\text{Lie}(M)$ via $\lambda$, and the weights are integers. The Lie algebras of $Z_M(\lambda)$ and $W^+_M(\lambda)$ may be identified with the weight subspaces of this action corresponding to the zero, positive and negative weights. It is shown in [29] Ch. 2 and App. C that $P_M(\lambda)$, $Z_M(\lambda)$ and $W^+_M(\lambda)$ are $k$-subgroups of $M$. Moreover, $W^-_M(\lambda)$ is a normal subgroup of $P_M(\lambda)$ and the product map

\[ Z_M(\lambda) \times W^+_M(\lambda) \to P_M(\lambda) \]

is a $k$-isomorphism of varieties.
A pseudo-parabolic $k$-subgroup of $M$ is a group of the form $P_{M}(\lambda)R_{a,k}(M)$ for some $\lambda$ as above where $R_{a,k}(M)$ denotes the maximal connected normal unipotent $k$-subgroup of $M$, \cite[Def. 2.2.1]{6}.

We also recall from \cite[Prop. 2.1.8(3)]{6} that the product map
\begin{equation}
W_{M}(\lambda) \times Z_{M}(\lambda) \times W_{M}^{+}(\lambda) \to M
\end{equation}
is an open immersion of $k$-schemes.

It is worth mentioning that these results are generalization to arbitrary groups of analogous and well known statements for reductive groups.

Let $M = M(k)$, and put
\begin{equation}
W_{M}^{+}(\lambda) = W_{M}^{+}(\lambda)(k), \text{ and } Z_{M}(\lambda) = Z_{M}(\lambda)(k).
\end{equation}
From (3.8) we conclude that $W_{M}^{-}(\lambda)Z_{M}(\lambda)W_{M}^{+}(\lambda)$ is a Zariski open dense subset of $M$, which contains a neighborhood of identity with respect to the Hausdorff topology.

For any $\lambda$ as above define
\begin{equation}
M^{+}(\lambda) := \langle W_{M}^{+}(\lambda), W_{M}^{-}(\lambda) \rangle.
\end{equation}

Lemma 3.2.

1. For any $\lambda$ as above, $M^{+}(\lambda)$ is a normal and unimodular subgroup of $M$.
2. There are only countably many subgroups of the form $M^{+}(\lambda)$ in $M$.

Combining results in \cite[App. C]{6} together with part (1) in the lemma one can actually conclude that there are only finitely many such subgroups. We shall only make use of the weaker statement above.

Proof. Part (1) is proved in \cite[Lemma 2.1]{27}. We now prove (2). First note if $\lambda_{1}, \lambda_{2} : G_{m} \to M$ are two homomorphisms so that $\lambda_{1} = g\lambda_{2}g^{-1}$ for some $g \in M$, then $M^{+}(\lambda_{1}) = gM^{+}(\lambda_{2})g^{-1}$. Therefore, by part (1) we have
\begin{equation}
M^{+}(\lambda_{1}) = M^{+}(\lambda_{2}) \text{ whenever } \lambda_{1} = g\lambda_{2}g^{-1} \text{ for some } g \in M.
\end{equation}

Let now $S$ be a maximal $k$-split $k$-torus in $M$. By \cite[Thm. C.2.3]{6} there is some $g \in M$ so that $g\lambda g^{-1} : G_{m} \to S$. The claim now follows from this, (3.10), and the fact that the finitely generated abelian group $X_{*}(S) = \text{Hom}(G_{m}, S)$ is countable.

Given any subfield $l \subset k$ so that $k/l$ is a finite extension we let $R_{k/l}$ denote the Weil’s restriction of scalars, see \cite[§A.5]{6}.

In the following let $G$ be a connected $k$-group and let $\Gamma \subset G$ be a discrete subgroup in $G = G(k)$. Furthermore, let $k' \subset k$ be a closed subfield and let $H$ be an absolutely almost simple, $k'$-isotropic, $k'$-group. Assume that $\varphi : H \times k' \to G$ is a nontrivial $k$-homomorphism, and put $E = \varphi(H(k'))$. We use in an essential way the following measure classification result by Alireza Salehi-Golsefidy and the third named author.

Theorem B (\cite[Theorem 6.9 and Corollary 6.10]{27}). Let $\nu$ be a probability measure on $G/\Gamma$ which is $E$-invariant and ergodic. Then, there exist
1. some $l = (k')^{q} \subset k$ where $q = p^{n}$, $p = \text{char}(k)$ and $n$ is a nonnegative integer,
2. a connected $l$-subgroup $M$ of $R_{k/l}(G)$ so that $M(l) \cap \Gamma$ is Zariski dense in $M$, and
3. an element $g_{0} \in G$,
such that $\nu$ is the $g_0Lg_0^{-1}$-invariant probability Haar measure on the closed orbit $g_0L\Gamma/T$ with

$$L = M^+(\lambda)(M(l) \cap \Gamma),$$

where

- the closure is with respect to the Hausdorff topology, and
- $\lambda : G_m \to M$ is a noncentral $l$-homomorphism, $M^+(\lambda)$ is defined in \textbf{[3.9]}, and $E \subset g_0M^+(\lambda)g_0^{-1}$.

3.3. A version of Borel density theorem. Let $k' \subset k$ be an infinite closed subfield. We recall from \textbf{[32]} Prop. 1.4 that the discompact radical of a $k'$-group is the maximal $k'$-subgroup which does not have any nontrivial compact $k'$-algebraic quotients. It is shown in \textbf{[32]} Prop. 1.4 that this subgroup exists and the quotient of the $k'$-points of the original group by the $k'$-points of the discompact radical is compact. Let $\mathbf{A}$ be a $k$-split torus. Let $A_{\text{sp}}^{k'} \subset \mathcal{R}_{k/k'}(\mathbf{A})(k') = A$ denote the $k'$-points of the maximal $k'$-split subtorus of $\mathcal{R}_{k/k'}(\mathbf{A})$.

Suppose $\mathbf{V}$ is a variety defined over $k'$ and assume that $\mathcal{R}_{k/k'}(\mathbf{A})$ acts on $\mathbf{V}$ via $k'$-morphisms. In particular, $A = \mathcal{R}_{k/k'}(\mathbf{A})(k')$ acts on $V = \mathbf{V}(k')$ via $k'$-morphisms.

**Lemma 3.3** (Cf. \textbf{[32]} Theorem 1.1). Let $(X, \eta)$ be an $A$-invariant ergodic probability space. Let $f : X \to V$ be an $A$-equivariant Borel map. Then there exists some $v_0 \in \text{Fix}_{\mathcal{A}_{\text{sp}}^{k'}}(V)$, so that $f_*\eta$ is the $A$-invariant measure on the compact orbit $Av_0$.

In particular, $f(x) \in Av_0$ for $\eta$-a.e. $x$.

**Proof.** This follows from \textbf{[32]} Thm. 1.1 in view of the fact that $A_{\text{sp}}^{k'}$ is the discompact radical of $\mathcal{R}_{k/k'}(\mathbf{A})$ as defined in \textbf{[32]}, see also \textbf{[32]} Thm. 3.6. \hfill \Box

3.4. Pinsker $\sigma$-algebra and unstable leaves. Throughout this section we assume $G$ is a $k$-isotropic semisimple $k$-group and let $\mathbf{A}$ be a $k$-split $k$-torus in $G$. Put $G = G(k)$ and $A = A(k)$. Let $\Gamma$ be a discrete subgroup of $G$ and put $X = G/\Gamma$.

Let $a \in A$ be a nontrivial element. Recall that for an $a$-invariant measure $\mu$ we define the Pinsker $\sigma$-algebra as

$$\mathcal{P}_a := \{B \in \mathcal{B} : h_\mu(a, \{B, X \setminus B\}) = 0\}.$$ 

It is the largest $\sigma$-algebra with respect to which $\mu$ has zero entropy, see \textbf{[34]} for further discussion.

Let us recall the following important and well known proposition; we outline the proof for the sake of completeness.

**Proposition 3.4.** The Pinsker $\sigma$-algebra, $\mathcal{P}_a$, is equivalent to the $\sigma$-algebra of Borel sets foliated by $W^+_G(a)$ leaves.

Note that the Pinsker $\sigma$-algebra for $a$ equals the Pinsker $\sigma$-algebra for $a^{-1}$, which shows that the proposition also applies similarly for $W^-_G(a)$.

**Proof.** Suppose $\mathcal{C}$ is any $\sigma$-algebra whose elements are foliated by $W^+_G(a)$ leaves. Let $p : (X, \mu) \to (Y, p_*\mu)$ be the corresponding factor map. Using the Abramov-Rokhlin conditional entropy formula and the relationship between entropy and leafwise measures, see \textbf{[14]}, we get the following

$$h(a, (Y, p_*\mu)) = 0.$$ 

The definition of the Pinsker $\sigma$-algebra then implies that $\mathcal{C} \subset \mathcal{P}_a$. 

For the converse we recall from [26] Sec. 9, see also [14], that there is a finite entropy generator, i.e. a countable partition $\xi$ of finite entropy such that $\bigvee_{n=-\infty}^{\infty} a^{-n} \xi$ is equivalent to the full Borel $\sigma$-algebra, and so that in addition the past is subordinate with respect to $W^+_G(a)$. That is to say that on the complement of a null set every atom of $\bigvee_{n=-\infty}^{0} a^{-n} \xi$ is an open subset of a $W^+_G(a)$-orbit. Hence, after removing a null set, any set measurable with respect to the tail $\bigcap_{k \in \mathbb{N}} \bigvee_{n=-\infty}^{0} a^{-n} \xi$ is a union of $W^+_G(a)$-orbits. Since $\mathcal{P}_a$ is equivalent to the tail of $\xi$ modulo $\mu$, the claim follows.

The following will be used in the course of the proof of Theorem 1.2.

**Lemma 3.5.** Let $X_i = G_i/\Gamma$ be as in Theorem 1.2. In particular, $G_i = G_i(k)$ where $G_i$ is a connected, simply connected, absolutely almost simple group defined over $k$ for $i = 1, 2$. Let $\mathbf{a} = (a_1, a_2) \in \mathcal{A}$ such that $\mathbf{a}$ generates an unbounded group, and suppose $\mu$ is an ergodic joining of the $A_i$-action on $(X_i, m_i)$, for $i = 1, 2$. Let $\mu = \int_X \mu^\nu_x \, d\mu(x)$ where $\mu^\nu_x$ denotes the conditional measure for $\mu$-a.e. $x$ with respect to the Pinsker $\sigma$-algebra $\mathcal{P}_a$. Then there exists a subset $X' \subset X_1 \times X_2$ with $\mu(X') = 1$ so that

$$\pi_{i*}(\mu^\nu_x) = m_i \text{ for all } x \in X' \text{ and } i = 1, 2.$$  

**Proof.** Let $P$ denote the pinsker factor of $X$ and let $\Upsilon : X \to P$ be the corresponding factor map. This is a zero entropy factor of $X$.

Put $Z = X_1 \times X_2 \times P$, and let

$$\nu = \int \mu^\nu_x \times \delta_{\Upsilon(x)} \, d\Upsilon_* \mu(x).$$

Let $p_i : Z \to X_i \times P$ be the natural projection. Then $p_{i*}\nu$ is a measure on $X_i \times P$ which projects to $m_i$ and $\Upsilon_* \mu$ for $i = 1, 2$. Now $(X_i, m_i)$ is a system with completely positive entropy. This follows, e.g., from Proposition 3.4 and the ergodicity of the action of $W^\pm(a_i)$; note that the latter holds since $G_i$ is connected, simply connected, and absolutely almost simple. [25] Ch. 1, Thm. 2.3.1, Ch. 2, Thm. 2.7]. However, $(P, \Upsilon_* \mu)$ is a zero entropy system, therefore, by disjointness theorem of Furstenberg [18], see also [20] Thm. 18.16] we obtain

$$p_{i*}\nu = m_i \times \Upsilon_* \mu. \quad (3.11)$$

Let us now decompose $p_{i*}\nu$ as

$$p_{i*}\nu = \int (p_{i*}\nu)_{(x_i, p)} \, dp_{i*}\nu.$$  

Then (3.11) implies that for $p_{i*}\nu$-almost every $(x_i, p)$ we have

$$(p_{i*}\nu)_{(x_i, p)} = m_i \times \delta_p.$$  

This in view of the definition of $\nu$ implies the claim.

3.5. **Leafwise measures.** We refer to [14] for a comprehensive treatment of leafwise measures.

Recall that $G$ is a $k$-isotropic semisimple $k$-group and let $A$ be a $k$-split $k$-torus in $G$. Let $S$ be a maximal $k$-split $k$-torus of $G$ which contains $A$. Let $\Phi(S, G)$ be the relative root system of $G$, and let $\Phi(A, G)$ denote the set of roots of $A$ as in §2.
Let $U$ be an $A$-normalized unipotent $k$-subgroup of $G$ contained in some $W_{\Gamma}(a)$. The leafwise measure $\mu^U_x$ along $U$ is defined for $\mu$-a.e. $x \in X$. For all such $x$ we put

$$S^U_x = \text{supp}(\mu^U_x) \quad \text{and} \quad \mathcal{I}^U_x = \{v \in U : v\mu^U_x = \mu^U_x\}.$$ 

The leafwise measures are canonically defined up to proportionality, and we write $u$ in which case we will use $\mu^U_x$, $S^U_x$, $\mathcal{I}^U_x$ to denote $\mu^U_{ux}$, $S^U_{ux}$, $\mathcal{I}^U_{ux}$ respectively.

**Lemma 3.6.** Under the above assumptions, a.s. $\mathcal{I}^U_x = \{v \in U : v\mu^U_x \propto \mu^U_x\}$.

**Proof.** This is true in general, but is particularly easy in the positive characteristic case: Suppose $u \in U$ is such that $u\mu^U_x \propto \mu^U_x$. Then $u\mu^U_x = \kappa \mu^U_x$ for some $\kappa > 0$. Since $U$ is unipotent, $u$ is torsion of exponent $p^n$ for some $n$, hence $\kappa p^n = 1$, which implies (since $\kappa > 0$) that $\kappa = 1$. $\square$

We recall some properties of leafwise measures which will be used throughout. Our formulation is taken from [13], see [24] as well as [14] and references there.

**Lemma 3.7.** Let $U$ be an $A$-normalized unipotent $k$-subgroup of $G$ contained in some $W_{\Gamma}(a)$. There is a conull subset $X' \subset X$ so that

1. For all $x \in X'$ the map $x \mapsto \mu^U_x$ is a measurable map. In particular, $\mu^U_x$ is defined for all $x \in X'$.
2. For every $x \in X'$ and every $u \in U$ so that $ux \in X'$, we have $\mu^U_x \propto (\mu^U_{ux})u$ where $(\mu^U_{ux})u$ denotes the push forward of $\mu^U_{ux}$ under the map $v \mapsto uv$.
3. For every $x \in X'$ we have $\mu^U_x(U[1]) = 1$ and $\mu^U_x(U[\epsilon]) > 0$ for all $\epsilon > 0$.
4. Suppose $\mu$ is $a$-invariant under some $a \in A$. Then for $\mu$-a.e. $x \in X$, we have $\mu^U_{ux} \propto (\mu^U_{ux} a^{-1})$.

**Lemma 3.8** (Cf. [13], §6). Let $a \in A$ be so that the Zariski closure of $\langle a \rangle$, $A'$ say, is $k$-isomorphic to $G_m$ and that $A'(k)/\langle a \rangle$ is compact. Suppose $\mu$ is $a$-invariant and let $U$ be an $A$-normalized unipotent $k$-subgroup of $G$ contained in $W_{\Gamma}(a)$. Let $Q$ be any compact open subgroup of $U$. Then for $\mu$-a.e. $x$, the Zariski closure of $\mathcal{I}^U_x \cap Q$ is normalized by $a$ and contains $\mathcal{I}^U_x$.

**Proof.** Let $E$ denote a countably generated $\sigma$-algebra that is equivalent to the $\sigma$-algebra of $a$-invariant sets. Then $(\mu^E_x)_y = \mu^E_{yx}$ for $\mu^E_x$-a.e. $y$ and $\mu$-a.e. $x$, see e.g. [14]. Therefore, we may assume that $\mu$ is $a$-ergodic.

Let $\mathcal{U}_0$ denote a fixed compact open subgroup of $U$. For any $n \in \mathbb{Z}$, define

$$\mathcal{U}_n = a^n \mathcal{U}_0 a^{-n}.$$ 

Then $\mathcal{U}_n \subset Q$ for large enough $n$, hence, it suffices to prove the lemma for $Q = \mathcal{U}_n$.

Let $X' \subset X$ be a conull set where Lemma 3.7 holds. For any $x \in X'$ and any $n \in \mathbb{Z}$ define

$$F_{x,n} = \text{The Zariski closure of } \mathcal{U}_n \cap \mathcal{I}^U_x.$$ 

Then $F_{x,n}$ is a $k$-group, see e.g. [34] Lemma 11.2.4(ii)].

Note also that $F_{x,n} \subset F_{x,m}$ whenever $n \geq m$. Therefore, there exists some $n_0 = n_0(x)$ so that $\dim F_{x,n} = \dim F_{x,n_0}$ for all $n \geq n_0$, where $\dim$ is the dimension as a $k$-group. Since the number of connected components of $F_{x,n_0}$ is finite, there exists $n_1 = n_1(x)$ so that $F_{x,n} = F_{x,n_1}$ for all $n \geq n_1$. Put $F_x := F_{x,n_1}$. 

The definition of $F_{x,n}$, in view of Lemma 3.7(4), implies that

$$F_{ax,n+1} = aF_{x,n}a^{-1}.$$ 

Therefore, we have

(3.12)  

$$F_{ax} = aF_xa^{-1}.$$ 

Let $k[G]$ denote the ring of regular functions of $G$. For every $x \in X'$, let $J_x \subset k[G]$ be the ideal of regular functions vanishing on $F_x$. Let $m(x)$ be the minimal integer so that $J_x$ is generated by polynomials of degree at most $m(x)$. In view of (3.12), we have $m(x) = m(ax)$. Since $\mu$ is $a$-ergodic, we have $x \mapsto m(x)$ is essentially constant. Replacing $X'$ by a conull subset, if necessary, we assume that $m(x) = m$ for all $x \in X'$.

Let $Y = \{ h \in k[G] : \deg(h) \leq m \}$. Using a similar argument as above, we may assume that $\dim(J_x \cap Y) = \ell$ for all $x \in X'$.

Let $f : X \to \text{Grass}(\ell)$, the Grassmannian of $\ell$-dimensional subspaces of $Y$, be the map defined by $f(x) = J_x \cap Y$ for all $x \in X'$. Then, $f$ is an $a$-equivariant, Borel map. Therefore, $\nu = f_*\mu$ is a probability measure on $\text{Grass}(\ell)$ which is invariant and ergodic for a $k$-algebraic action of $a$ on $\text{Grass}(\ell)$. Hence,

$$\bar{\nu} = \int_{A'(k)/a} b_{u} \nu \, db$$

is an $A'(k)$-invariant, ergodic probability measure on $\text{Grass}(\ell)$ equipped with an algebraic action of $A'(k)$. By [32, Thm. 3.6], $\bar{\nu}$ is the delta mass at an $A'(k)$-fixed point which implies $\nu = \bar{\nu}$ is the delta mass at an $A'(k)$-fixed.

Therefore, $f$ is essentially constant. Using the definition of $f$, we get that $aF_xa^{-1} = F_x$ for $\mu$-a.e. $x$. This, (3.12), and the ergodicity of $\mu$ imply that $F_x = F$ for $\mu$-a.e. $x$.

Let now $C \subset X'$ be a compact subset with $\mu(C) > 1 - \epsilon$ so that

- $n_1(x) \leq N_1$ for all $x \in C$,
- $F_x = F$ for all $x \in C$.

By pointwise ergodic theorem for almost every $x \in X$ there is a sequence $m_i \to \infty$ so that $a^{m_i}x \in C$ for all $i$. Let now $x$ be such a point, and let $u \in T_{x}^{U}$. By Lemma 3.7(4) we have

$$a^{m_i}ua^{-m_i} \in \bigcup_{N_1} \cap T_{a^{m_i}x}^{U} \subset F(k).$$

for all large enough $i$. Since $F(k)$ is normalized by $a$, we get that $u \in F(k)$. □

From this point on we assume that $\mu$ is $A$-invariant. We recall the product structure for leafwise measures, see [9]. Our formulation is taken from [14, Prop. 8.5 and Cor. 8.8].

**Lemma 3.9.** Fix some $a \in A$. Let $H = T \ltimes U$ where $U < W_G(a)$ and $T < Z_G(a)$. Then there exists a conull subset $X' \subset X$ with the following properties.

1. For every $x \in X'$ and $h \in H$ such that $hx \in X'$ we have $\mu_x^h \propto (\mu_{hx}^T)t$ where $h = ut = tu'$ for $t \in T$ and $u, u' \in U$.
2. For every $x \in X'$ we have $\mu_x^U \propto \iota_* (\mu_x^T \times \mu_x^U)$ where $\iota(t, u) = tu$ is the product map.
3. Assume further that $T$ centralizes $U$. Then for all $x \in X'$ and $t \in T$ so that $tx \in X'$ we have $\mu_x^U \propto \mu_x^T$. 

Lemma 3.12. Hence applying Lemma 3.6 we deduce if \( \kappa, \kappa \) for \( \iota \) where (3.13) by e.g. [3, §2.5] both Lyapunov weights contained in \( \Psi \). Then for \( \mu \)-a.e. \( x \in X \),

\[
\mu_x^\Psi \propto \iota_*(\mu_x^{[\alpha_1]} \times \cdots \times \mu_x^{[\alpha_k]}).
\]

For the proof cf. e.g. [9] or [14, §8].

Lemma 3.11. Suppose \( \mu \) is an \( A \)-invariant ergodic probability measure. Let \( \Psi \subset k\Phi(A, G) \) be a positively closed subset, and assume that \( \alpha, \beta \in \Psi \) are linearly independent roots. Let \( \Psi' \subset \Psi \) be those elements of \( \Psi \) that can be expressed as a linear combination of \( \alpha \) and \( \beta \) with strictly positive coefficients. Then \( \Psi' \) is also closed and for \( \mu \)-a.e. \( x \) we have

\[
[S_x^\alpha, S_x^\beta] \subset T_x^\Psi \quad \text{and} \quad [S_x^{\alpha_1}, S_x^{\alpha_2}] \subset T_x^{\Psi'}
\]

Proof. By e.g. [3, §2.5] both \( \Psi' \) and \( \Psi' \cup \{\alpha, \beta\} \) are positively closed subset of \( k\Phi(A, G) \). Let [\( \gamma_1 \), \( \ldots \), \( \gamma_\ell \)] be an enumeration of all course Lyapunovs in \( \Psi \setminus (\Psi' \cup \{\alpha, \beta\}) \).

Then by Proposition 3.10

\[
(3.13) \quad \mu_x^\Psi \propto \iota_*(\mu_x^{[\alpha]} \times \mu_x^{[\beta]} \times \mu_x^{[\gamma_1]} \times \cdots \times \mu_x^{[\gamma_\ell]})
\]

\[
\propto \iota_*(\mu_x^{[\beta]} \times \mu_x^{[\alpha]} \times \mu_x^{[\gamma_1]} \times \cdots \times \mu_x^{[\gamma_\ell]}),
\]

where \( \iota \) is the product map.

Let now \( f \in C_c(V^\Psi) \), then (3.13) and Fubini’s theorem implies that

\[
\int f(g) d\mu_x^W = \kappa \int f(v_\beta v_\alpha v_\psi v_\gamma, \ldots) d\mu_x^{V_\alpha} d\mu_x^{V_\beta} d\mu_x^{V_\psi} d\mu_x^{V_\gamma} \ldots d\mu_x^{V_\gamma}
\]

\[
= \kappa' \int f(v_\beta v_\alpha v_\psi v_\gamma, \ldots) d\mu_x^{V_\alpha} d\mu_x^{V_\beta} d\mu_x^{V_\psi} d\mu_x^{V_\gamma} \ldots d\mu_x^{V_\gamma}
\]

\[
= \kappa' \int f(v_\beta v_\alpha v_\psi v_\gamma, \ldots) d\mu_x^{V_\alpha} d\mu_x^{V_\beta} d\mu_x^{V_\psi} d\mu_x^{V_\gamma} \ldots d\mu_x^{V_\gamma}
\]

for \( \kappa, \kappa' \) independent of \( f \).

From this we get for \( \mu_x^{[\alpha]} \)-a.e. \( v_\alpha \in V_\alpha \) and \( \mu_x^{[\beta]} \)-a.e. \( v_\beta \in V_\beta \),

\[
\mu_x^{\Psi'} \propto [v_\beta, v_\alpha] \mu_x^\Psi
\]

hence applying Lemma 3.6 we deduce \([v_\beta, v_\alpha] \mu_x^{\Psi'} = \mu_x^{\Psi'}\). Applying Proposition 3.10 again we concluded that also \([v_\beta, v_\alpha] \mu_x^{\Psi} = \mu_x^{\Psi}\).

Since \( T_x^\Psi \) is a (Hausdorff) closed subgroup of \( V^\Psi \) it follows that

\[
(3.14) \quad [S_x^\alpha, S_x^\beta] \subset T_x^\Psi \text{ almost surely.}
\]

Lemma 3.12 (Cf. [12], §8). Let \( \mu \) be an \( A \)-invariant probability measure on \( X \). There is a conull subset \( X' \subset X \) with the following property. Let \( \Psi \subset k\Phi(A, G) \) be a positively closed subset such that \( V_\Psi \subset W_a^G (a) \) for some \( a \). Then for all \( x \in X' \), if \( v = \prod v_\alpha \in \mathcal{T}_x^\Psi \), with \( v_\alpha \in V_\alpha \) for all \( [\alpha] \subset \Psi \), then \( v_\alpha \in \mathcal{T}_x^{[\alpha]} \) for all \( [\alpha] \).
Proof. We say a root $\alpha \in \Psi$ is exposed (cf. [14]) if there exists an element $b \in A$ so that $\alpha(b) = 1$ and $|\beta(b)| < 1$ for all $\beta \in \Psi \setminus \{\alpha\}$. If $\Psi$ is as above then clearly it has at least one exposed Lyapunov weight $\alpha$ and that $\Psi' = \Psi \setminus \{\alpha\}$ is also positively closed. Moreover, for any $v_\alpha \in V_{[\alpha]}$ and $v' \in V_{\Psi'}$ it holds that $[v_\alpha, v'] \in V_{\Psi'}$.

Suppose $v_\alpha v' \in T^\Psi_x$ with $v_\alpha \in V_{[\alpha]}$ and $v' \in V_{\Psi'}$. Then

$$\int f(g) d\mu^\Psi_x = \kappa \int f(g, g') d\mu^V_{\alpha} \, d\mu^\Psi_x$$

$$= \int f(v_\alpha v' g) d\mu^\Psi_x$$

$$= \kappa \int f(v_\alpha v' g, g') d\mu^V_{\alpha} \, d\mu^\Psi_x$$

$$= \kappa \int f(v_\alpha g, v'[v', g]) d\mu^V_{\alpha} \, d\mu^\Psi_x$$

for some $\kappa$ independent of $f$.

It follows by uniqueness of decomposition that for $\mu^V_{\alpha}$-a.e. $g_\alpha$,

$$v'[v', g] \mu^\Psi_x \propto \mu^\Psi_x$$

hence by Lemma 3.6 we have that $v'[v', g] \in T^\Psi_x$. It follows that $v_\alpha \mu^V_{\alpha} = \mu^V_{\alpha}$ and $v_\alpha \in T^{V}_{\alpha}$. Moreover, as for a.e. $x$ the identity is in the support of $\mu^V_{\alpha}$ by Lemma 3.7 (3) we have that $v' \in T^{\Psi'}_x$. The lemma now easily follows by induction on the cardinality of $\Psi$. □

For any $W^+_G(a)$ we fix some increasing sequence of compact open subgroups $K_n$ with $W^+_G(a) = \bigcup_n K_n$ and some decreasing sequence of compact open subgroups $O_n \subset K_1$ with $\{e\} = \bigcap_n O_n$. Then any closed subgroup $I < W^+_G(a)$ is determined by the finite subgroups $I \cap K_n/O_n < K_n/O_n$, which allows us to speak of measurability of a subgroup depending on $x \in X$.

Lemma 3.13. Let $a \in A$. Then $T^W_G(a)$ is $\mathcal{P}_a$-measurable.

Proof. We prove this for $W^-_G(a)$, the proof in the other case is similar. There is a full measure set $X' \subset X$ so that whenever $x, w, x' \in X'$ we have

$$\mu^W_G(a) \propto \mu^W_G(a) w.$$ 

This implies $T^W_G(a) = T^W_G(a)$. The lemma now follows from Proposition 3.4. □

Lemma 3.14. Let $\alpha \in \Phi(A, G)$ be such that $V_{[\alpha]} < W^-_G(a)$. Then the subgroup $T^V_x$ is $\mathcal{P}_a$-measurable.

Proof. In view of Proposition 3.4 it suffices to show that $x \mapsto T^V_x$ is constant along $W^-_G(a)$-leaves almost surely, which is an immediate corollary of Lemma 3.13 and Lemma 3.12. □

4. High entropy part of Theorem 1.1

We now start the proof of Theorem 1.1. Throughout $\{\Phi(A, G) \cup \Phi(X) \mu \}$ denotes an ergodic $A$-invariant measure on $G/\Gamma$. 

"
For any $\alpha \in \Phi$ there exists a $k$-embedding $\varphi_\alpha : \text{SL}_2 \to \text{SL}_d$ so that $U_\alpha = \varphi_\alpha(U)$ and $U_{-\alpha} = \varphi_\alpha(U^-)$ where $U^\pm$ denote the upper and lower triangular unipotent subgroups of $\text{SL}_2$. We let $H_\alpha = \text{Im}(\varphi_\alpha)$.

Let $T$ denote the diagonal subgroup of $\text{SL}_2$. Let $t_\alpha = \begin{pmatrix} \theta & 0 \\ 0 & \theta^{-1} \end{pmatrix} \in T$ be an element so that $\alpha(\varphi_\alpha(t_\alpha)) = \theta^2$ and $\beta(\varphi_\alpha(t_\alpha)) = \theta^\varepsilon$ with $\varepsilon \in \{-1,0,1\}$ for all $\beta \in \Phi \setminus \{\pm \alpha\}$. Put

$$a_\alpha := \varphi_\alpha(t_\alpha).$$

Then $U_\alpha \subset W^+_G(a_\alpha)$.

Given a root $\alpha \in \Phi$ we define

$$\Phi^+_\alpha := \{\beta \in \Phi : U_\beta \subset W^+(a_\alpha)\},$$

and put $\Phi^-_\alpha = -\Phi^+_\alpha$.

**Lemma 4.1.** Let $\alpha \in \Phi$ and let $\beta \in \Phi^-_\alpha \setminus \{-\alpha\}$. The following hold.

1. $\beta + \alpha \in \Phi^+_\alpha$.
2. If $\beta + na \in \Phi$ for some integer $n \geq 1$, then $n = 1$.
3. $\alpha \in \Phi^-_\beta$.

**Proof.** Assertions (1) and (3) are general facts, which follow from the definitions and hold for any roots system. Part (2) is a special feature of root systems of type $A$ which is the case we are concerned with here. \qed

A well-known theorem by Ledrappier and Young [23] relates the entropy, the dimension of conditional measures along invariant foliations, and Lyapunov exponents, for a general $C^2$ map on a compact manifold, and in [26, §9] an adaptation of the general results to flows on locally homogeneous spaces is provided. The following is taken from [8] Lemma 6.2, see also [10] Prop. 3.1 and [14]. For any root $\alpha \in \Phi$ there exists $s_\alpha(\mu) \in [0,1]$ so that for any $a \in A$ with $|\alpha(a)| \geq 1$ we have

$$h_\mu(a, U_\alpha) = s_\alpha(\mu) \log |\alpha(a)|$$

where $h_\mu(a, U_\alpha)$ denotes the entropy contribution of $U_\alpha$. Indeed $s_\alpha(\mu)$ are defined as the local dimension of the leafwise measure along $\alpha$ as we now recall. Define

$$D_\mu(a_\alpha, U_\alpha)(x) = \lim_{|n| \to \infty} \frac{\log(\mu_{\alpha}^n(a_\alpha^n U_\alpha[1] a^-_\alpha n))}{n},$$

the limit exists by [9] Lemma 9.1, and define $h_\mu(a_\alpha, U_\alpha) = \int D_\mu(a_\alpha, U_\alpha) \, d\mu$, the entropy contribution of $U_\alpha$. Since $D_\mu(a_\alpha, U_\alpha)(x)$ is $A$-invariant and $\mu$ is $A$-ergodic, we have

$$h_\mu(a_\alpha, U_\alpha) = D_\mu(a, U)(x) \text{ for } \mu\text{-a.e. } x.$$

Therefore, $s_\alpha(\mu) = \frac{1}{2} D_\mu(a, U)(x)$ for $\mu\text{-a.e. } x$.

Moreover, the following properties hold.

1. $s_\alpha(\mu) = 0$ if and only if $\mu^a_\alpha$ is delta mass at the identity,
2. $s_\alpha(\mu) = 1$ if and only if $\mu^a_\alpha$ is the Haar measure on $U_\alpha$,
3. for any $a \in A$ we have

$$h_\mu(a) = \sum s_\alpha(\mu) \log^+ |\alpha(a)|$$

where $\log^+(\ell) = \max\{0, \log \ell\}$.

The following is the main result of this section.
Proposition 4.2 (Cf. [15], Theorem 5.1). Let $\alpha \in \Phi$ be so that $\mu_\alpha^\circ$ is nontrivial for $\mu$-a.e. $x$. Then at least one of the following holds.

1. $\mu_\alpha^2 = \delta_\alpha$ for all $\beta \in \Phi_\alpha^\perp \setminus \{\alpha\}$ and $\mu$-a.e. $x$.
2. $\mathcal{I}_x^\alpha$ are nondiscrete subgroups of $U_{x,\alpha}$ for $\mu$-a.e. $x$.

Proof. Recall that for $\SL(d)$ the roots $\alpha$ can be identified with ordered tuples of indices $(i,j) \in \{1, \ldots, d\}$ satisfying $i \neq j$. We use the local dimensions $s_\alpha = s_{(i, j)}$ to define a relation on $\{1, \ldots, d\}$. In fact we write $i \leq j$ if $i = j$ or $s_{(i, j)} > 0$, and $i \prec j$ if $i \leq j$ and $\alpha(i) \in \Phi(s_{(i, j)})$ implies $\alpha(i) \prec \alpha(j)$.

It follows that $\sim$ is an equivalence relation on $\{1, \ldots, d\}$ and that $\leq$ descends to a partial order on the quotient by $\sim$. Let us write $[i]$ for the equivalence classes with respect to $\sim$. To simplify matters we may assume (by applying a suitable element of the Weyl group) that for every $i$ the equivalence class $[i] = \{m, m+1, m+2, \ldots, n\}$ consist of consecutive indices for some $m \leq i$ and $n \geq i$. Moreover, we may assume that $i \leq j$ for two indices implies either $i \sim j$ or $i < j$.

We now prove that $i \leq j$ implies $i \sim j$. Otherwise, we claim that we can choose a diagonal matrix $a$ with two different eigenvalues (equal to powers of $\theta$) such that the leaflwise measures of the stable horospherical subgroup $W_G^\circ(a)$ are nontrivial and the leaflwise measures of the unstable horospherical subgroup $W_G^\circ(a)$ are trivial almost surely. More precisely assuming $[i] = \{m, m+1, m+2, \ldots, n\}$ (so that by the indirect assumption $j > n$) we define $a$ to be the diagonal matrix with the first $m$ eigenvalues equal to $\theta^{d-m}$ and the last $d - m$ eigenvalues equal to $\theta^{-m}$.

By assumption $s_{(i, j)} > 0$, which implies $h_\mu(a) > 0$ by (s_\alpha^{-3}), the choice of $a$, and since $i \leq n < j$. However, for all $k \leq n < \ell$ we have $s_{k, k} = 0$ (by our ordering of the indices) and hence $h_\mu(a^{-1}) = 0$ also by (s_\alpha^{-3}). This contradiction proves the claim that $i \leq j$ implies $i \sim j$.

Given a root $\alpha = (i, j)$ with $s_\alpha > 0$ there are now two options. Either $[i] = \{i, j\}$ or the cardinality of $[i]$ is at least three. In the first case we have $s_{(i, \ell)} = s_{(\ell, j)} = s_{(\ell, j)} = 0$ for all $\ell \notin \{i, j\}$ and translating this to the language of roots we obtain (1). In the second case let $\ell \in [i] \setminus \{i, j\}$ and apply Lemma 3.11 for the roots $(i, \ell), (\ell, j)$ to see that $\mathcal{I}_{x(i, \ell)}^\circ$ (and similarly also $\mathcal{I}_{x(\ell, j)}^\circ$) is a nondiscrete group almost surely.

5. Low entropy part of Theorem [13]

We use the notation introduced in §4. In view of Proposition 4.2, the following is the standing assumption for the rest of this section. There is a root $\alpha \in \Phi$ so that

$$s_\alpha = s_{-\alpha} > 0 \quad \text{and} \quad s_\beta = 0$$

for any $\beta \in \Phi_\alpha^\perp \setminus \{\alpha, -\alpha\}$.

Let us put

$$Z_\alpha := C_G(U_\alpha) \cap C_G(U_{-\alpha}) = C_G(H_\alpha).$$

We have the following.

Lemma 5.1 (Cf. [10], Lemma 4.4(1)). There is a null set $N$ so that for all $x \in X \setminus N$ we have

$$W_G^\circ(a_\alpha)x \cap (X \setminus N) \subseteq U_\alpha x.$$
Proof. In view of Lemma 3.9 there is a null set $N_1$ so that for all $x \in X \setminus N_1$ we have $\mu_x^W(a_\alpha)$ is a product of the leafwise measures $\mu_x^\beta$ for all $U_\beta \subset W_G^+(a_\alpha)$. By (5.1) it follows that
\begin{equation}
\text{supp}(\mu_x^W(a_\alpha)) = \text{supp}(\mu_x^\alpha_u) \text{ for all } x \in X \setminus N_1.
\end{equation}

Recall also that there is a null set $N_2$ so that if $x, ux \in X \setminus N_2$ for some $u \in W_G(a_\alpha)$, then
\begin{equation}
\mu_x^W(a_\alpha) \propto \mu_{ux}^W(a_\alpha) u.
\end{equation}

Let $x \in X \setminus (N_1 \cup N_2)$, then by (5.2) we have $\text{supp}(\mu_x^W(a_\alpha)) \subset U_\alpha$. Therefore by (5.3) we get $u \in U_\alpha$, this finishes the proof of the first claim if we put $N = N_1 \cup N_2$.

To see the last assertion, let $x$ and $u$ be as in the statement. In view of the first part in the lemma, we have $u \in U_\alpha$. Our assumption and the fact that $U_\alpha$ is a commutative group give
\[ u\mu_x^\alpha = \mu_{ux}^\alpha u \propto \mu_x^\alpha \text{ for } \mu\text{-a.e. } x. \]

Now one argues as in the proof Lemma 3.11 and gets $u \in \mathcal{I}_x^\alpha$. \hfill \Box

We also recall the following definition from [13].

Definition 5.2. Let $H, Z \subset G$ be closed subgroups of $G$. We say the leafwise measures $\mu_x^H$ are locally $Z$-aligned modulo $\mu$ if for every $\varepsilon > 0$ and neighborhood $B_\varepsilon^Z \subset Z$ of the identity, there exists a compact set $Q$ with $\mu(Q) > 1 - \varepsilon$ and some $\delta > 0$ so that for every $x \in Q$ we have
\[ \{ y \in Q : \mu_x^H = \mu_y^H \} \cap B_x(\delta) \subset B_{\varepsilon\delta}^Z. \]

The following is a direct corollary of the main result of [13], proved there explicitly also for the positive characteristic case.

Theorem 5.3 (Cf. [13], Theorem 1.4). Under the assumption (5.1) one of the following holds.

1. \text{(LE-1)} $\mu_x^\alpha$ is locally $Z_\alpha$-aligned modulo $\mu$.
2. \text{(LE-2)} There exists an $a_\alpha$-invariant subset $X_{\text{inv}}(\alpha) \subset X$ with $\mu(X_{\text{inv}}(\alpha)) > 0$ so that for all $x \in X_{\text{inv}}(\alpha)$ there is an unbounded sequence $\{u_{x,m}\} \subset W_G^+(a_\alpha)$ such that $\mu_x^\alpha = \mu_{ux_{x,m}}^\alpha$.

6. Proof of Theorem 6.1

Recall the notation in §2.1 in particular, $k = K_v$ where $K$ is a global function field and $v$ is a place of $K$. Throughout $\Gamma = \text{SL}(d, \mathcal{O})$ where $\mathcal{O}$ denotes the ring of $v$-integers in $K$.

Put $\text{GL}(n, \mathfrak{o})_m = \ker(\text{GL}(n, \mathfrak{o}) \to \text{GL}(n, \mathfrak{o}/\theta^{-m}\mathfrak{o}))$.

Lemma 6.1 (Cf. [10], Lemma 5.3). For any positive integer $n$ there exists some $m = m(n) \geq 1$ with the following property. Let $a = \text{diag}(a_1, \ldots, a_n)$ with
\[ |v(a_i) - v(a_j)| > m \text{ for all } i \neq j. \]

Then $ga$ is diagonalizable over $k$, for all $g \in \text{GL}(n, \mathfrak{o})_m$. Moreover, if $a'_1, \ldots, a'_n$ are the eigenvalues of $ga$, then it is possible to order them so that $v(a_i) = v(a'_i)$ for all $i$. 

Proof. Let \( \tilde{k}_n \) be the composite of all field extensions of \( k \) of degree at most \( n! \). Then, the characteristic polynomial of any element in \( GL(n, k) \) splits over \( \tilde{k}_n \). Moreover, \( \tilde{k}_n \) is a local field, i.e. \( \tilde{k}_n/k \) is a finite extension. We let \( v \) denote the unique extension of \( v \) to \( \tilde{k}_n \).

We begin with the following observation. There is some \( m_n \geq 1 \) so that every \( g \in GL(n, o)_{m_n} \) can be decomposed as \( g = g^- g^0 g^+ \) with \( g^\pm \in W^\pm \cap GL(n, o)_1 \) and \( g^0 \in A \cap GL(n, o)_1 \), where \( W^+ \) (resp. \( W^- \)) is the group of upper (resp. lower) triangular unipotent matrices. Indeed, in view of (3.8), the product map is a diffeomorphism from

\[
(W^- \cap GL(n, o)_1) \times (A \cap GL(n, o)_1) \times (W^+ \cap GL(n, o)_1)
\]

onto its image. Therefore the claim follows from the inverse function theorem.

We show the lemma holds with \( m = m_n \). First note that after conjugating by a permutation matrix we can assume \( v(a_1) > \ldots > v(a_n) \). Let \( g \in GL(n, o)_m \) and let \( b_1, \ldots, b_n \) be the eigenvalues of \( ga \) listed with multiplicity and ordered so that \( v(b_1) \geq \cdots \geq v(b_n) \). Note that \( b_i \in \tilde{k}_n \) for all \( 1 \leq i \leq n \).

Let \( \| \cdot \| \) be the max norm on the \( i \)-th exterior power \( \wedge^i \tilde{k}_n \), with respect to the standard basis \( \{ e_{j_1} \wedge \cdots \wedge e_{j_i} \} \). Denote by \( \| \cdot \| \) the operator norm of the action of \( GL(n, \tilde{k}_n) \) on \( \wedge^i \tilde{k}_n \) for \( 1 \leq i \leq n \).

Choosing a basis of \( \tilde{k}_n \) consisting of the generalized eigenvectors for \( ga \) we get

\[
\lim _\ell \| \wedge^i (ga)^\ell \|^ {1/\ell} = |b_1 \cdots b_i| \quad \text{for all } i.
\]

We now claim

\[
\| \wedge^i (ga)^\ell \| = \| \wedge^i a^\ell \| = |a_1 \cdots a_i|^\ell \quad \text{for all } \ell.
\]

The second equality in the claim is immediate. To see the first equality note that if \( g_1, g_2 \in GL(n, o)_m \), then

\[
g_1 a g_2 g_2^- g_2^+ a = g_1 (a g_2^- a^{-1}) a^2 g_2^0 (a^{-1} g_2^- a).
\]

Moreover, since \( g^\pm \in GL(n, o)_1 \) and \( v(a_i) - v(a_{i+1}) > m \) for all \( i \), we have \( a g_2^- a^{-1} \) and \( g_2^0 a^{-1} g_2^+ a \) belong to \( GL(n, o)_m \).

Using this we get

\[
(ga)^\ell = g_{\ell} a^\ell g_{\ell}',
\]

where \( g_{\ell}, g_{\ell}' \in GL(n, o)_{m} \) and \( a_{\ell}' \in GL(n, o)_1 \) for all \( \ell \). This implies \( 6.2 \).

Now \( 6.1 \) and \( 6.2 \) imply that \( v(a_i) = v(b_i) \) for all \( 1 \leq i \leq n \), in particular, \( v(b_i) \neq v(b_j) \) whenever \( i \neq j \). This implies \( b_i \)'s are distinct and hence \( ga \) is a semisimple element. We now show \( b_i \in \tilde{k}_n \) for all \( i \). Recall that \( b_1, \ldots, b_n \) are roots of the characteristic polynomial of \( ga \) which is polynomial with coefficients in \( k \). For every \( 1 \leq i \leq n \) let \( Gal(b_i) = \{ b_j : j \text{ is a Galois conjugate of } b_i \} \). Then \( \{ b_1, \ldots, b_n \} \) is a disjoint union of \( \bigsqcup_{i=1}^r Gal(b_i) \) for some \( \{ i_1, \ldots, i_r \} \subseteq \{ 1, \ldots, n \} \). Since \( v(b_i) \neq v(b_j) \) whenever \( i \neq j \) and Galois automorphisms preserve the valuation, we get that \( Gal(b_i) = \{ b_i \} \) for all \( i \). This establishes the final claim in the lemma. \( \square \)

**Proposition 6.2.** Suppose \( \Gamma = SL(d, O) \). Then \( \mu_0^o \) is not locally \( Z_o \)-aligned modulo \( \mu \). In particular, under the assumption \( 6.1 \), we have that (LE-2) in Theorem 5.3 holds.
Proof. We recall the argument from the proof of Theorem 5.1 in [10]. Let $m$ be large enough so that the conclusion of Lemma 6.1 holds with $n = d - 2$. Without loss of generality we may assume $\alpha(\text{diag}(a_1, \ldots, a_d)) = a_1a_2^{-1}$. Define

$$\tilde{B} = \left\{ \begin{pmatrix} r & 0 & 0 \\ 0 & r & 0 \\ 0 & 0 & A \end{pmatrix} : r \in 1 + \theta^{-2}o, A \in \text{GL}(d-2,o) \right\} \subset \text{GL}(d,o).$$

Put $B := \tilde{B} \cap Z_\alpha$; we note that $B$ is a compact open subgroup of $Z_\alpha$.

Let $a = \text{diag}(a_2, a_3, \ldots, a_d) \in A \cap Z_\alpha$ with $v(a_2) \neq 0$, and $|v(a_i) - v(a_j)| > m$ for all $i > j \geq 2$. In particular, we have $\alpha(a) = 1$.

Suppose (LE-1) holds. Then by Poincaré recurrence for $\mu$-a.e. $\Gamma \in G/\Gamma$ there exist a sequence $\ell_i \to \infty$ so that $a_{\ell_i}g \Gamma \in Bg \Gamma$ for all $i$.

Hence for all $i$ there exist some $\gamma_i \in \Gamma$ and some $h_i \in B$ so that $h_ia_{\ell_i} = g\gamma_ig^{-1}$.

Now Lemma 6.1 implies the following. If $\ell_i$ is large enough and we write

$$g\gamma_ig^{-1} = h_ia_{\ell_i} = \begin{pmatrix} r_i & 0 & 0 \\ 0 & r_i & 0 \\ 0 & 0 & A_i \end{pmatrix},$$

then $A_i$ is diagonalizable whose eigenvalues have the same valuation as $a_{\ell_i}$ for all $3 \leq j \leq d$.

Therefore, (LE-1) in Theorem 5.3 implies that there exists an element $\gamma \in \Gamma$ with the following properties

- $\gamma$ is a semisimple element,
- no eigenvalue of $\gamma$ is a root of unity,
- all of the eigenvalues of $\gamma$ are simple except exactly one eigenvalue which has multiplicity 2.

Since $\gamma$ is semisimple, and the coefficients of the characteristic polynomial of $\gamma$ are in $K$, there is a finite separable extension $\tilde{K}$ of $K$ which contains the eigenvalues of $\gamma$, see [2, 4.1(c)]. Moreover, the eigenvalues of $\gamma$ are algebraic units in the integral closure of $O$ in $\tilde{K}$ and no eigenvalue of $\gamma$ is a root of unity. Therefore, none of the eigenvalues of $\gamma$ lies in $K$.

In particular, the eigenvalue with multiplicity 2 is not in $K$ and is separable over $K$. Since any Galois conjugate of this eigenvalue is also an eigenvalue of $\gamma$ with the same multiplicity, we get a contradiction with the fact that $\gamma$ has only one non-simple eigenvalue. \qed

6.1. Pinsker components have non-trivial invariance. We begin with the following corollary of the results in §4 and §5.

Corollary 6.3. Under the assumptions of Theorem 1.1 we have the following. There exists some $\alpha \in \Phi$ and a $\mu$-conull subset $X_{\text{inv}}(\alpha) \subset X$ so that $I_x^{\pm \alpha}$ are nondiscrete for all $x \in X_{\text{inv}}(\alpha)$.

Proof. Since $h_\mu(a) > 0$ for some $a \in A$ there exists some $\alpha \in \Phi$ with $s_\alpha > 0$. In view of Proposition 4.2, the claim in the corollary holds true almost surely unless $\alpha$ satisfies [5.1].

However, in this case Theorem 5.3 and Proposition 6.2 imply that (LE-2) must hold true. Put $X' = \{x \in X : I_x^{\pm \alpha}$ is nontrivial$\}$. By (LE-2) and Lemma 5.1 we get
that $X'$ has positive measure. Moreover, $X'$ is $A$-invariant in view of Lemma [3.7](4).

Since $\mu$ is $A$-ergodic we get that $\mu(X') = 1$. Now choose $\ell \in \mathbb{Z}$ such that $X'_\ell = \{ x \in X' : \mathcal{I}_x^{\pm \alpha} \cap U_{\alpha}[\ell] \text{ is nontrivial} \}$ satisfies $\mu(X'_\ell) > 0$. Applying ergodicity and the pointwise ergodic theorem we see that a.e. $x \in X$ satisfies that there exists some $\alpha \in A$ and infinitely many $n \geq 0$ and infinitely many $n \leq 0$ such that $a^n(x) \in X'_\ell$. Using Lemma [3.7](4) this implies the corollary. 

Throughout the rest of this section, we fix some root $\alpha$ so that the conclusion of Corollary [6.3] holds true, and put $X_{\text{inv}} := X_{\text{inv}}(\alpha)$.

For any root $\beta$ let $A_\beta$ denote the one parameter diagonal subgroup which is the Zariski closure of the group generated by $a_\beta$. For the sake of notational convenience we will denote $A_\beta = \{ \beta(t) : t \in k^x \}$ where $a_\beta = \beta(\theta)$.

Let $\delta$ be a root so that $V_{[\alpha]}$ is contained in $W^+_{\delta}(a_\delta)$. For the rest of this section denote the Pinsker $\sigma$-algebra $\mathcal{P}_{a_\delta}$ for $a_\delta$ simply by $\mathcal{P}$. We further take a decomposition

\begin{equation}
\mu = \int_X \mu^\mathcal{P}_x \, d\mu(x),
\end{equation}

where $\mu^\mathcal{P}_x$ denotes the $\mathcal{P}$ conditional measure for $\mu$ almost every $x \in X$.

Since $\mu$ is $A$-invariant and $A$ commutes with $a_\delta$, the $\sigma$-algebras $\mathcal{P}$ is $A$-invariant. Hence we get

\begin{equation}
a_x \mu^\mathcal{P}_x = \mu^\mathcal{P}_{a_x} \quad \text{for } \mu\text{-a.e. } x \in X
\end{equation}

Recall the definition of $H_\alpha = \varphi_\alpha(\text{SL}(2, k))$ from the beginning of §4. For every $x \in X$ we put

\begin{equation}
\mathcal{H}_x := \{ g \in H_\alpha : g \mu^\mathcal{P}_x = \mu^\mathcal{P}_x \}.
\end{equation}

It follows from (6.4) that

\begin{equation}
\mathcal{H}_{a_x} = a\mathcal{H}_x a^{-1}
\end{equation}

for all $a \in A$ and $\mu$-a.e. $x$.

**Corollary 6.4.** $(\mathcal{I}_x^\alpha, \mathcal{I}_x^{-\alpha})$ is Zariski dense in $H_\alpha$ as a $k$-group for $\mu$-a.e. $x \in X_{\text{inv}}$. Moreover, $(\mathcal{I}_x^\alpha, \mathcal{I}_x^{-\alpha}) \subset \mathcal{H}_x$.

**Proof.** The first claim follows from Corollary [6.3]. To see the second claim, note that by Lemma [3.14] we know that $\mathcal{I}_x^{\pm \alpha}$ is measurable with respect to $\mathcal{P}$. Equivalently, the groups $\mathcal{I}_x^{\pm \alpha}$ are (almost surely) constant on the atoms of a countably generated $\sigma$-algebra $\mathcal{P}'$ that is equivalent to $\mathcal{P}$. We now decompose $\mu$ as in (6.3) into conditional measures for the $\sigma$-algebra $\mathcal{P}'$ and take the leafwise measures of $\mu^\mathcal{P}_x$ for the subgroup $U_\alpha$. However, Proposition [3.4] implies that we may assume the atoms with respect to $\mathcal{P}'$ are unions of $U_\alpha$-orbits. This implies in turn for the leafwise measure that $(\mu^\mathcal{P}_x)^y U_\alpha = \mu^\mathcal{P}_y$ for $\mu$-a.e. $y$ and $\mu$-a.e. $x$ (see [17, Prop. 5.20] and [14, Prop. 7.22] for a similar argument). Fixing one such $x$ we obtain that $(\mu^\mathcal{P}_x)^y U_\alpha$ is almost surely invariant under $\mathcal{I}_y^\alpha = \mathcal{I}_y^\alpha$. However, this implies by the relationship between the measure and its leafwise measures that $\mu^\mathcal{P}_x$ is invariant under $\mathcal{I}_x^\alpha$. Since $\mu^\mathcal{P}_x$ is $\mu$-almost surely we may apply the same argument for $\mathcal{I}_x^{-\alpha}$. Therefore, $\mathcal{I}_x^{\pm \alpha} \subset \mathcal{H}_x$ for $\mu$-a.e. $x$. 

\qed
6.2. Algebraic structure of $\mathcal{H}_x$. Recall from the beginning of §4 that $H_\alpha = \varphi_\alpha(\mathrm{SL}_2(k))$. Put $U_{\pm\alpha}(\mathfrak{o}_x) = \varphi_\alpha(U_{\pm}(\mathfrak{o}_x))$ where $U^+$ (resp. $U^-$) denotes the group of upper (resp. lower) triangular unipotent matrices in $\mathrm{SL}_2$.

Note that $H_\alpha = \langle U_\alpha, U_{-\alpha} \rangle$. By Corollary 6.4 for $\mu$-a.e. $x$ we have $\langle \mathcal{I}_x^\alpha, \mathcal{I}_x^{-\alpha} \rangle \subset \mathcal{H}_x$. Define

$$Q_\alpha := \langle \mathcal{H}_x \cap U_\alpha(\mathfrak{o}_x), \mathcal{H}_x \cap U_{-\alpha}(\mathfrak{o}_x) \rangle.$$  

Put

$$X_P := \{ x \in X : Q_\alpha \text{ is Zariski dense in } H_\alpha \text{ and } Q_\alpha \cap U_{\pm\alpha} \text{ are infinite} \}.$$  

Corollary 6.4 and the above definitions imply that $X_P \cap X_{\text{inv}}$ is conull in $X_{\text{inv}}$. In particular, Corollary 6.3 implies that $\mu(X_P) = 1$.

Note that for all $x \in X_P$, the group $Q_\alpha$ satisfies the conditions of Theorem A.1 in Section 3.1. For any $x \in X_P$ define

$$k'_x := \text{the field generated by } \{ \text{tr}(\rho(g)) : g \in Q_\alpha \}$$

and put

$$k_x := \begin{cases} k'_x & \text{if } \text{char}(k) \neq 2, \\ \{ c : c^2 \in k'_x \} & \text{if } \text{char}(k) = 2. \end{cases}$$

Theorem A.1 then implies that there exist

(C-1) a unique (up to a unique isomorphism) $k$-isogeny $\varphi_x : \mathrm{SL}_2 \times_{k_x} k \to \mathrm{SL}_2$ whose derivative vanishes nowhere, and

(C-2) some non-negative integer $m_x$

so that

$$\varphi_x(\mathrm{SL}(2, \mathfrak{o}_{x, m_x})) \subset Q_\alpha \subset \varphi_x(\mathrm{SL}(2, k_x))$$

where $\mathfrak{o}_x$ is the ring of integers in $k_x$ and

$$\mathrm{SL}(2, \mathfrak{o}_x) := \ker(\mathrm{SL}(2, \mathfrak{o}_x) \to \mathrm{SL}(2, \mathfrak{o}_x/\varpi_x^m \mathfrak{o}_x)).$$

with $\varpi_x$ a uniformizer in $\mathfrak{o}_x$.

Let us put

$$E_x := \varphi_x(\mathrm{SL}(2, k_x)).$$

We will use without further remark the following, which is a consequence of the implicit function theorem. The group generated by $U_\pm(\varpi_x^m \mathfrak{o}_x)$ is an open subgroup of $\mathrm{SL}(2, \mathfrak{o}_x)_{m_x}$, e.g. a direct computation yields this group contains $\mathrm{SL}(2, \mathfrak{o}_x)_{2m}$.

**Lemma 6.5.**

1. The map $x \mapsto k_x$ is a Borel map on $X_P$.
2. The equation (6.11) defines a Borel map, $x \mapsto E_x$, on $X_P$.

**Proof.** The map $x \mapsto Q_\alpha$ is a Borel map from a conull subset of $X$ into the set of closed subgroups of $H_\alpha(\mathfrak{o}_x)$. This and (6.9) imply that $x \mapsto k_x$ is a Borel map on the conull set $X_P$, as we claimed in (1).

By part (1) the map $x \mapsto k_x$ is a Borel map. Also recall from Lemma 3.1(1) that $E_x = \langle E_x \cap U_\alpha, E_x \cap U_{-\alpha} \rangle$. Therefore, part (2) follows if we show the map $x \mapsto E_x \cap U_{\pm\alpha}$ is a Borel map. Note, however, $E_x \cap U_{\pm\alpha}$ is a one dimensional $k_x$-vector vector subspace of $U_{\pm\alpha}$, thought of as a $k_x$ subspace. Hence,

$$E_x \cap U_{\pm\alpha} = k_x \cdot (Q_\alpha \cap U_{\pm\alpha}),$$
which implies the claim.

Lemma 6.6.

1. The map \( x \mapsto k_x \) is essentially constant.
2. The map \( x \mapsto E_x \) is an \( A \)-equivariant Borel map on a conull subset of \( X \).

Proof. We claim \( k_x \subset k_{ax} \) for all \( a \in A \). First let us note that by symmetry, this also implies that \( k_{ax} \subset k_x \). Therefore, it implies that the map \( x \mapsto k_x \) is \( A \)-invariant; since \( \mu \) is \( A \)-ergodic we get part (1).

We now show the claim. Let \( m_x \) be as in (C-2). Recall from (6.6) that there is a full measure set \( X' \subset X \) so that for all \( x \in X' \) and all \( a \in A \) we have \( H_{ax} = aH_xa^{-1} \).

Now for any \( a \) there exists some \( m_{x,a} \geq m_x \) so that if \( m \geq m_{x,a} \), then

\[ (6.12) \]

\[ a\varphi_x(\text{SL}(2, \sigma_x)m)a^{-1} \subset Q_{ax}. \]

Define \( l_x(m) \) to be the field generated by \( \{\text{tr}(\rho(g)) : g \in \varphi_x(\text{SL}(2, \sigma_x)m)\} \). Then

\[ (6.13) \]

\[ l_x(m) = k_x \text{ for all } m \geq m_x. \]

Indeed this is true for the field generated by \( \{\text{tr}(\rho(g)) : g \in \text{SL}(2, \sigma_x)m\} \). Since \( \varphi_x \) has nowhere vanishing derivative and there are no nonstandard isogenies for type \( A_1, [28 \text{ Prop. 1.6}], \) we get \( \rho_1 = \rho_2 \circ \varphi_x \) where \( \rho_1 \) and \( \rho_2 \) are the adjoin representation on the source and the target of \( \varphi_x \). This implies (6.13).

It follows from (6.12) and (6.13) that \( k_x \subset k_{ax} \), as we claimed.

Let us now prove part (2). By part (1) there is an \( A \)-invariant conull set \( X' \) and a subfield \( k' \) so that \( k_x = k' \) for all \( x \in X' \). Let \( \sigma' \) denote the ring of integers in \( k' \).

We note that the same proof as in the proof of Lemma 6.5(2) implies that \( E_x \cap U_{\pm \alpha} \) is the Zariski closure of \( C \cap U_{\pm} \) in \( R_{k/k'}(\text{SL}_d) \) for any nontrivial open subgroup \( C \) of \( Q_x \).

Let now \( a \in A \) and \( x \in X' \). Then by (6.12) we have

\[ a\varphi_x(\text{SL}(2, \sigma')m)a^{-1} \subset Q_{ax} \]

for all \( m \geq m_{x,a} \). Since \( aH_xa^{-1} = H_{ax} \) and \( \varphi_x(\text{SL}(2, \sigma')m) \) is open in \( Q_x \) by (6.10), we thus get that \( a\varphi_x(\text{SL}(2, \sigma')m)a^{-1} \) is open in \( Q_{ax} \) for all \( m \geq m_{x,a} \).

Since \( U_{\pm \alpha} \) are normalized by \( A \), for all \( a \in A \) and all \( m \geq m_{x,a} \) we have

\[ a\varphi_x(\text{SL}(2, \sigma')m)a^{-1} \cap U_{\pm \alpha} = a(\varphi_x(\text{SL}(2, \sigma')m) \cap U_{\pm \alpha})a^{-1}. \]

Taking Zariski closure in \( R_{k/k'}(\text{SL}_d) \) we get that

\[ a(E_x \cap U_{\pm \alpha})a^{-1} = E_{ax} \cap U_{\pm \alpha}. \]

This and Lemma 3.1(1) imply the claim.

Proposition 6.7. For \( \mu \)-a.e. \( x \in X_P \) we have \( E_x \subset H_x \).

Proof. Let \( x \in X_P \) and put \( A'_x = E_x \cap A \). In view of Lemma 6.6(2) we have

\[ (6.14) \]

\[ A'_{ax} = E_{ax} \cap A = aE_ka^{-1} \cap A = a(E_x \cap A)a^{-1} = A'_x \]

for \( \mu \)-a.e. \( x \) and all \( a \in A \). Since \( \mu \) is \( A \)-ergodic we get that \( x \mapsto A'_x \) is essentially constant. Let us denote by \( A' \) this essential value.

Then by Lemma 3.1(2) we have \( A' \) is an unbounded subgroup of \( A_\alpha = H_\alpha \cap A \).

The group \( A_\alpha \) is a one dimensional \( k \)-split \( k \)-torus, therefore, \( A_\alpha/A' \) is compact. For any \( s \in k \) we let \( \hat{\alpha}(s) \in A_\alpha \) be the cocharacter associated to \( \alpha \) and evaluated at \( s \), i.e. \( \hat{\alpha}(s) \) is the diagonal matrix with eigenvalues \( s, s^{-1} \) and 1 with multiplicity \( d-2 \) so that \( \alpha(\hat{\alpha}(s)) = s^2 \). This implies that there exist some \( \ell > 0 \) and some \( r \in o_v \), so
that if we put $s := \theta^i r$, then $\hat{\alpha}(s) \in E_x$. In particular, $\hat{\alpha}(s)$ normalizes both $E_x \cap U_\alpha$ and $E_x \cap U_{-\alpha}$.

For every $\varepsilon > 0$ there is subset $X_P(\varepsilon) \subset X_P$ with $\mu(X_P(\varepsilon)) > 1 - \varepsilon$ so that the map

$$x \mapsto \mu_x^P$$

is continuous on $X_P(\varepsilon)$. Now by Poincaré recurrence, for $\mu$-a.e. $x \in X_P(\varepsilon)$ there is a sequence $n_{x,i} \to \infty$ so that $\hat{\alpha}(s^{n_{x,i}}) \in X_P(\varepsilon)$ for all $i$ and $\hat{\alpha}(s^{n_{x,i}}) x \to x$. Then

$$\lim_{i \to \infty} \mathcal{H}_{\hat{\alpha}(s^{n_{x,i}}) x} \subset \mathcal{H}_x.$$ 

Recall from (6.10) that $Q_x \cap U_\alpha$ contains an open compact subgroup of $E_x \cap U_\alpha$. Therefore, using (6.6) we get that

$$\forall x \in X_P(\varepsilon).$$

Choosing a sequence $\varepsilon_n \to 0$ we get that $E_x \cap U_\alpha \subset \mathcal{H}_x$ for $\mu$-a.e. $x \in X_P$.

Similarly, we get $E_x \cap U_{-\alpha} \subset \mathcal{H}_x$ for $\mu$-a.e. $x \in X_P$. Recall from Lemma 6.6(1) that $E_x$ is generated by $E_x \cap U_{\pm \alpha}$. Therefore $E_x \subset \mathcal{H}_x$ for $\mu$-a.e. $x \in X_P$. □

6.3. Applying the measure classification for semisimple groups. We now apply the measure classification theorem due to Alireza Salehi-Golsefidy and the third named author (Theorem B from Section 3.2).

**Lemma 6.8.** Let $\mu$ be as in Theorem [L]. Then there exist a closed infinite subfield $l < k$ and an algebraic $l$-subgroup $M < R_{k/l}(\text{SL}_d)$ such that $M(l) \cap \Gamma$ is Zariski dense in $M$ over $l$, and a noncentral cocharacter $\lambda : G_m \to M$ over $l$ so that the topological group

$$L = \text{M}^+(\lambda)(M(l) \cap \Gamma)$$

satisfies that $L/(L \cap \Gamma)$ has finite volume. Moreover, for $\mu$-a.e. $x$, the $E_x$-ergodic component of $\mu_x^P$ equals $h\nu_L$ for some $h \in \text{SL}(d,k)$ so that $x = h\Gamma$ and $\nu_L$ is the homogeneous measure on $L/(L \cap \Gamma)$.

**Proof.** Let $k'$ denote the essential value of the map $x \mapsto k_x$, see Lemma 6.6(1). In view of Proposition 6.7 for $\mu$-a.e. $x$ the measure $\mu_x^P$ is invariant under $E_x$.

Since the $\sigma$-algebra $\mathcal{P}$ is $A$-invariant we have $a\mu_x^P = \mu_{ax}^P$ for all $a \in A$ and $\mu$-a.e. $x$. Moreover, by Lemma 6.6(2) we have $E_{ax} = aE_x a^{-1}$ for $\mu$-a.e. $x$. Therefore, if we let

$$\mu_x^P = \int \nu_z \, d\mu_x^P(z)$$

be the ergodic decomposition of $\mu_x^P$ with respect to $E_x$ (where for $\mu_x^P$-a.e. $z$ we let $\nu_z$ denote the $E_x$-ergodic components of $\mu_x^P$) then

$$\mu_{ax}^P = \int a_* \nu_z \, d\mu_x^P(z)$$

is the ergodic decomposition of $\mu_{ax}^P$ with respect to $E_{ax}$.

Applying Theorem B in Section 3.2 we conclude that for $\mu_x^P$-a.e. $z$ the measure $\nu_z$ is described as follows.

There exist

(B-1) $l_z = (k')^{q_z} \subset k$ where $q_z = p^{n_z}$, $p = \text{char}(k)$ and $n_z \geq 1$, 

where $\text{char}(k)$ denotes the characteristic of $k$. 

This finishes the proof of the lemma.

(B-2) a connected \( l_z \)-subgroup \( M_z \) of \( R_{k/l_z}(SL_d) \) so that \( M_z(l_z) \cap \Gamma \) is Zariski dense in \( M_z \), and

(B-3) an element \( g_z \in G \),
such that \( \nu_z \) is the \( g_z L_z g_z^{-1} \)-invariant probability Haar measure on the closed orbit \( g_z L_z \Gamma / \Gamma \) with

\[
L_z = M_z^+(\lambda_z)(M_z(l_z) \cap \Gamma)
\]

where

- the closure is with respect to the Hausdorff topology, and
- \( \lambda_z : G_m \to M_z \) is a noncentral \( l_z \)-homomorphism, \( M_z^+(\lambda_z) \) is defined in \((3.9)\), and \( E_z \subset M_z^+(\lambda_z) \).

For any \( z \) where \( \nu_z \) is described as above, let \( (l_z, [M_z], [M_z^+(\lambda_z)]) \) be the corresponding triple where \([\bullet] \) denotes the \( \Gamma \) conjugacy class. This is well defined and we will refer to it as the \textit{triple associated to} \( z \). Given a triple \((l, [M], [M^+(\lambda)])\) put

\[
\mathcal{G}(l, [M], [M^+(\lambda)]) = \{ z \in X : (l, [M], [M^+(\lambda)]) \text{ is associated to } z \}.
\]

Note that there are only countably many such triples. Indeed there are only countably many closed subfields \( l \subset k' \) as in Theorem B(1), also there are only countably many \( M \) as in Theorem B(2). For any such \( l \) and \( M \) there are only countably many choices of \( M^+(\lambda) \) by Lemma \([32]2\). Therefore, there exists a triple \((l, [M], [M^+(\lambda)])\) such that

\[
\mu(\mathcal{G}(l, [M], [M^+(\lambda)])) > 0.
\]

Note, however, that in view of \((6.16)\) we have \( \mathcal{G}(l, [M], [M^+(\lambda)]) \) is \( A \)-invariant. This, together with the fact that \( \mu \) is \( A \)-ergodic, implies that

\[
\mu(\mathcal{G}(l, [M], [M^+(\lambda)])) = 1.
\]

This finishes the proof of the lemma.

We let \( l, M \) and \( L := M^+(\lambda)(M(l) \cap \Gamma) \) be as in Lemma \([6.8\]

(6.17) \( N := \) the Zariski closure of \( N_G^\prime(M(l)) \cap \Gamma \) in \( G' \)

where \( G' := R_{k/l}(SL_d) \) and \( G' := SL(d, k) \). Therefore, \( N \) is defined over \( l \), see e.g. \([33] \) Lemma 11.2.4(ii)]. In view of (B-2) above we have

(6.18) \( M \subset N^0 \) and \( N \subset N_G^\prime(M) \).

where \( N^0 \) denotes the connected component of the identity in \( N \).

\( \text{Lemma 6.9.} \) \textbf{We let} \( A^p_l \) \textbf{be the group of} \( l \)-\textit{points of the maximal} \( l \)-\textit{split torus subgroup of} \( R_{k/l}A \). \textbf{Then there exists some} \( g_0 \in SL(d, k) \) \textbf{so that} \( A^p_l \subset g_0 N(l)g_0^{-1} \) \textbf{and} \( \overline{A g_0 \Gamma/\Gamma} = \text{supp}(\mu) \).

\textit{Proof.} Recall that \( L \Gamma \) is a closed subset of \( G \) and for \( \mu \)-a.e. \( x \) and \( \mu_x^p \)-a.e. \( z \) we have

(6.19) \( \text{supp}(\nu_\gamma) = g L \Gamma / \Gamma \)

for some \( g \in G \). We note that the element \( g \) is not well defined, however, the set \( g L \Gamma \) is well defined. This, in view of (B-2), determines the set \( g M(l) \Gamma \) as the smallest set of the form \( R(l) \Gamma \) where \( R \) is an \( l \)-subvariety so that \( \nu_\gamma(R(l) \Gamma / \Gamma) > 0 \), see [27] Thm. 6.9 also the original [26] Prop. 3.2. Let now \( g, g' \in G \) be such that \( g M(l) \Gamma = g' M(l) \Gamma \). Then

\[
M(l) \subset \bigcup_\gamma g^{-1} g' M(l) \gamma.
\]
Hence, by Baire category theorem, there is some $\gamma_0$ so that $M(l) \cap g^{-1}g'M(l)\gamma_0$ is open in $M(l)$. Since $M$ is Zariski connected, any open (in Hausdorff topology) subset of $M(l)$ is Zariski dense in $M$, [25, Ch. 1, Prop. 2.5.3]. This and equality of the dimensions imply that $M(l) = g^{-1}g'M(l)\gamma_0$. Therefore, $g^{-1}g'm_0\gamma_0 = 1$ for some $m_0 \in M(l)$ and we get

$$M(l) = g^{-1}g'M(l)\gamma_0 = \gamma_0^{-1}M(l)\gamma_0.$$  

That is $\gamma_0 \in N_G(M(l)) \cap \Gamma$ and

$$g^{-1}g' = \gamma_0^{-1}m_0^{-1} \in (N_G(M(l)) \cap \Gamma)M(l).$$

Hence, by (6.17) and (6.18) we have

$$g^{-1}g' \in (N_G(M(l)) \cap \Gamma)M(l) \subset N(l).$$

Let $N = N(l)$ and $G' = G'(l) = SL(d,k)$. Then, by (6.20), we get a Borel measurable map $f$ from $\mathcal{G}(l,M,M^+(\lambda))$ to $G'/N = SL(d,k)/N$ defined by $f(x) = g_0N$.

The above discussion, in view of (6.16), implies that $f$ is an $A$-equivariant Borel map, where the action of $A$ on $SL(d,k)/N$ is induced from the natural action of $R_{k/l}(A)$ on $G'/N$.

Now by Lemma 3.3, there exists some

$$g_0N \in Fix_{A^p_{l'}}(SL(d,k)/N)$$

so that $f_*\mu$ is the $A$-invariant measure on the compact orbit $A_{g0}N$. Using the Birkhoff ergodic theorem for the action of $A$ on $X$ and the compactness of the orbit $A_{g0}N$, we can choose the representative $g_0 \in SL(d,k)$ so that $A_{g0}\Gamma/\Gamma = \text{supp}(\mu)$. Let us recall that $Fix_{A^p_{l'}}(SL(d,k)/N) = \{gN : g^{-1}A^p_{l'}g \subset N\}$. In particular, $g_0$ satisfies

$$g_0^{-1}A^p_{l'}g_0 \subset N,$$

as we claimed. \hfill \Box

6.4. The algebraic $K$-groups $F$ and $H$. While the groups $M < N$ are still somewhat mysterious at this stage, we can describe their $k$-Zariski closure quite precisely.

**Lemma 6.10.** With the notations as in Theorem 3.1, let $F$ be a noncommutative algebraic subgroup of $SL_d$ so that $F(k) \cap \Gamma$ is Zariski dense in $F$ and $A' = A \cap g_0^{-1}F(k)g_0$ is cocompact in $A$. Then:

1. $g_0A_0^{-1} \subset F$,
2. $F$ has no $K$-rational character for any purely inseparable algebraic field extension $\bar{K}$ of $K$,
3. $F$ is a reductive $K$-group,
4. $F(k) \cap \Gamma$ is a lattice in $F(k)$, and
5. the commutator group $[F,F]$ is nontrivial, simply connected and almost $K$-simple.
6. $[F,F](k) \cong \prod_{i=1}^n SL(d_0,k)$ with $d = nd_0$.

We will assume without loss of generality that the group $g_0^{-1}[F,F](k)$ equals the subgroup consisting of $n$ block matrices along the diagonal.
Proof: First note that since $F(k) \cap \Gamma$ is Zariski dense in $F$, we have $F$ is defined over $K$, [33 Lemma 11.2.4(ii)]. Since $A/A'$ is compact and $A$ is Zariski connected and $k$-split, we have that $A'$ is Zariski dense in $A$. Since also $g_0 A' g_0^{-1} \subset F(l_0)$ we obtain $g_0 A g_0^{-1} \subset F$.

Let $\bar{K}$ be a finite purely inseparable extension of $K$. Recall that $k = K_v$ for a fixed place $v$ of $K$. Let $\bar{v}$ be the unique place of $\bar{K}$ over $v$ and let $\bar{O}$ be the ring of $\bar{v}$-integers in $\bar{K}$. Suppose $\chi$ is an arbitrary $K$-rational character of $F$. Then

$$\chi(\Gamma \cap F) \subset \chi(F(\bar{O})) \subset \bar{O}^\times.$$ 

Note that any element in $\bar{O}^\times$ is a $\bar{w}$-unit for all places $\bar{w}$ in $\bar{K}$ — this is tautological for $\bar{w} \neq \bar{v}$ and follows for $\bar{w} = \bar{v}$ from the product formula. Therefore, $\bar{O}^\times$ is a finite group consisting of roots of unity. This implies that there is a finite index subgroup $\Lambda \subset \Gamma \cap F$ so that $\chi(\Lambda) = 1$. Since $F$ is connected and $\Gamma \cap F$ is Zariski dense in $F$ the group $\Lambda$ is also Zariski dense in $F$. This implies $\chi$ is trivial on $F$ as claimed in (2).

We note that part (2) and [5] Thm. 1.3.6 imply part (4) directly. Below we give an argument using (3) which avoids the full force of [5] Thm. 1.3.6. In particular, the classification of pseudo reductive groups in [6] which is used to resolve the main difficulties in [5] is not needed here.

We now prove part (3). Let $\bar{K}$ be a finite purely inseparable extension of $K$ so that $R_u(F)$ is defined and splits over $\bar{K}$, see [2] 18.4 and 15.5. Restricting the adjoint representation of $F$ to the Lie algebra of $R_u(F)$ and taking the determinant we obtain a $\bar{K}$-character. If $R_u(F)$ is nontrivial, this character is also nontrivial since $F$ contains the maximal torus $S$. Therefore, (3) follows from (2).

Part (4) follows from (2), (3), and [21]. Note that the absence of a unipotent radical (defined over $k$ or not) makes the necessary arguments in our case much simpler.

For the rest of the argument we fix a maximal $K$-torus $S$ in $F$ which is $k$-split, see [6] Cor. A.2.6]. Note that by [6] Thm. C.2.3], there is some $g \in F(k)$ so that

$$g S g^{-1} = g_0 A g_0^{-1}.$$ 

We now establish (5). First note that $F$ is not commutative so $[F, F]$ is nontrivial. Let $K'$ be a separable field extension of $K$ such that $S$ splits over $K'$. Therefore, there exists some $g_1 \in \text{SL}_{d_1}(K')$ so that $g_1 S g_1^{-1}$ is the full diagonal subgroup of $\text{SL}_{d_1}$. Moreover, let $S_0 \subset S$ be the central torus of $F$. Then

$$g_1 [F, F] g_1^{-1} \subset g_1 [Z_{\text{SL}_{d_1}}(S_0), Z_{\text{SL}_{d_1}}(S_0)] g_1^{-1} = \prod_i \text{SL}_{d_i}$$

for some integers $d_1, d_2, \ldots$ (that depend on the subgroup $g_1 S_0 g_1^{-1}$). However since $S \subset F$, the (absolute) rank of $[F, F]$ equals $d - 1 - \dim(S_0) = \sum_i (d_i - 1)$. Since $[F, F]$ is semisimple and $\prod_i \text{SL}_{d_i}$ has no proper semisimple subgroup of the same rank, we get $g_1 [F, F] g_1^{-1} = \prod_i \text{SL}_{d_i}$. Let $W_1, \ldots$ be the various irreducible subspaces for the action of $[F, F]$ on the $d$-dimensional vector space that are defined over $K'$ and correspond to the various blocks of $g_1 [F, F] g_1^{-1}$. As $F$ is nonabelian at least one of the subspace, say $W_1$, has dimension $\geq 2$. Let $W$ be the sum of $W_i$ and all its Galois images. Then $W$ is invariant under $F$ and defined over $K$; recall that $K'/K$ is separable. Since $F$ has no $K$-rational characters, we see that $W$ has full
dimension. Otherwise the determinant of the restriction of $\mathbf{F}$ to $\mathbf{W}$ gives a $K$-character, which is nontrivial since $\mathbf{S}$ is a maximal torus. This implies that $[\mathbf{F}, \mathbf{F}]$ is semisimple and almost $K$-simple, hence $d_i = d_j$ for all $i, j$. □

Define

$$F := \text{the Zariski closure of } N(l) \cap \Gamma \text{ in } \text{SL}_d.$$  \hfill (6.22)

Note that $F$ is defined over $K$ and hence over $k$, see [33, Lemma 11.2.4(ii)].

**Lemma 6.11.**

1. $N(l) \subset F(k)$, and hence $N(l)$ is Zariski dense in $F$,
2. $F$ satisfies the conditions in Lemma 6.10.

**Proof.** Let us first note that part (1) implies (2). To see this recall that by (6.18) we have $E \subset M(l) \subset N(l)$ hence $F$ is noncommutative. Also by (6.21) we have $g_0^{-1} A_0^p g_0 \subset N(l) \subset F(k)$ and $A_0^p$ is cocompact in $\mathcal{A}$.

We now prove (1). It follows from the definition (6.22) that $N(l) \cap \Gamma \subset F(k) = \mathcal{R}_{k/l}(F)(l) \subset G'(l)$. Therefore, by (6.17) we have $N \subset \mathcal{R}_{k/l}(F)$. Taking $l$ points we get part (1). □

Similarly put

$$H := \text{the connected component of the identity in the Zariski closure of } M(l) \cap \Gamma \text{ in } \text{SL}_d.$$  \hfill (6.23)

Note that $H$ is defined over $K$ and hence over $k$.

**Lemma 6.12.**

1. $M(l) \subset H(k)$, and hence $M(l)$ is Zariski dense in $H$,
2. $[F, F] = H$,
3. $H$ is almost $K$-simple.
4. $H(k) \cong \prod_{d} \text{SL}(d_0, k)$ where $d = nd_0$.

**Proof.** The same argument as in the proof of Lemma 6.11 in view of (B-2) implies part (1).

By (6.18) we have $g M(l) g^{-1} = M(l)$ for all $g \in N(l)$. Hence by part (1) and Lemma 6.11 we have $H$ is a normal subgroup of $F$. Moreover, since $E \subset M(l)$ we have $H$ is non-commutative. As was mentioned above, $H$ is a $K$-subgroup of $F$. Hence by Lemma 6.11(2) and Lemma 6.10(5) we have

$$[F, F] \subset H.$$  \hfill (6.24)

We now show the other inclusion. In view of Lemma 6.11 and Lemma 6.10 we have $g_0 \mathbf{R}(k) \Gamma / \Gamma$ is a closed orbit with finite $g_0 \mathbf{R}(k) g_0^{-1}$ invariant finite measure for $R = F, [F, F]$. Moreover, by the choice of $g_0$ in Lemma 6.9 we have

$$\mu \text{ is supported on } g_0 \mathbf{R}(k) \Gamma / \Gamma.$$  \hfill (6.25)

Since $E \subset [F, F]$ and any $E$-ergodic measure is supported on $g_0 [F, F](k) \Gamma / \Gamma$, we get that $M(l) \subset [F, F](k)$. This completes the proof of part (2) thanks to part (1) and (6.24).

The fact that $H$ satisfies part (3) follows from part (2) and Lemma 6.11. It, moreover, satisfies part (4) thanks to part (2) and Lemma 6.10(6). □
Let us put \( A_H = A \cap g_0 H(k) g_0^{-1} \). In view of Lemmas 6.11 and 6.12 we see that \( g_0 H(k) g_0^{-1} \) has a block structure. Put \( C_H = g_0 C(F(k)) g_0^{-1} \). Then \( A' := A_H C_H \) is a cocompact subgroup of \( A \). We have the following.

**Lemma 6.13.** We can decompose the measure as follows
\[
\mu = \int_{A/\text{Stab}(\eta)} a_\ast \eta \, da
\]
where \( da \) is the Haar measure on the compact group \( A/\text{Stab}(\eta) \), and \( \eta \) is an \( A_H \)-ergodic component of \( \mu \) which is supported on \( g_0 H(k) \Gamma / \Gamma \). Moreover we have
\[
\eta = \int \nu_z \, d\eta(z).
\]
**Proof.** Recall from (6.25) that \( \mu \) is supported on the closed orbit \( g_0 F(k) \Gamma / \Gamma \). Hence, \( C_H \cap g_0 \Gamma g_0^{-1} \) acts trivially on \( \text{supp}(\mu) \). Moreover, by Lemma 6.11 and Lemma 6.10(4) we have that \( C(F(k)) \Gamma / \Gamma \) is compact. This and the fact that \( A/A'' \) is compact implies that
\[
(6.26) \quad A/A_H (C_H \cap g_0 \Gamma g_0^{-1})
\]
is a compact group. Therefore the \( A_H (C_H \cap g_0 \Gamma g_0^{-1}) \)-ergodic decomposition of \( \mu \) can be written as
\[
\int_{A/A_H (C_H \cap g_0 \Gamma g_0^{-1})} a_\ast \eta \, da
\]
where \( \eta \) is an \( A_H (C_H \cap g_0 \Gamma g_0^{-1}) \)-invariant measure on \( g_0 H(k) \Gamma / \Gamma \). This implies the decomposition of \( \mu \) as in the lemma.

For the final claim we note that the above discussion also shows that \( B^{A_H} \subset P \), where \( B^{A_H} \) is the \( \sigma \)-algebra of \( A_H \)-invariant sets. Hence the conditional measures \( \mu^P_x \) for the Pinsker \( \sigma \)-algebra can be obtained by double conditioning, i.e.
\[
\mu^P_y = (\mu^B_{A_H})^P_y
\]
for \( \mu \)-a.e. \( x \) and \( \mu^B_{A_H} \)-a.e. \( y \). Again because of compactness of \( (6.26) \) and the equivariance properties of the conditional measures it suffices to consider one of the conditional measure \( \eta = \mu^B_{A_H} \). For the Pinsker conditional measure \( \eta^P_y \) we have considered in (6.15) a decomposition into ergodic components for the group \( E_y \). These ergodic components have been completely described in Lemma 6.8. The lemma follows by integration over \( \eta \).

The following proposition describes the algebraic structure of the group \( L \).

**Proposition 6.14.** Let \( n \) be as in Lemma 6.13(4). Then there exist
\begin{enumerate}
\item A collection \((l_i : 1 \leq i \leq n)\) of closed subfields of \( k \),
\item For every \( 1 \leq i \leq n \) a connected, simply connected, absolutely almost simple \( l_i \)-group \( H_i \) and an isomorphism \( \varphi_i : H_i \times_1 k \rightarrow \text{SL}_{d_0} \) (where \( \text{SL}_{d_0} \) is considered as the \( i \)th block subgroup corresponding to the indices \((i-1)d_0 + 1, \ldots, id_0\))
\end{enumerate}
so that \( L = \prod_{i=1}^n \varphi_i(H_i(l_i)) \subset H(k) \)

**Proof.** In view of Lemma 6.12(3) and (4), the groups \( M \) and \( H \) satisfy the conditions in [27, §7]. Therefore [27, Thm. 7.1], which in turn relies heavily on [6] [28] [22], implies the following. There exist
(a) a collection \( (l_i : 1 \leq i \leq r) \) of closed subfields of \( k \),
(b) for every \( 1 \leq j \leq n \) some \( 1 \leq i(j) \leq r \) and a continuous field embedding
\( \tau_j : l(i(j)) \rightarrow k \),
(c) for every \( 1 \leq i \leq r \) a connected, simply connected, absolutely almost simple
\( l_i \)-group \( H_i \) (which is a form of \( SL_{d_0} \)),
(d) for every \( i \in \{1, \ldots, r\} \) there exists some \( j \in \{1, \ldots, n\} \) with \( i(j) = i \),
(e) an isomorphism \( \varphi : \prod_{i=1}^{r} H_i \times_{\tau(\oplus_{i=1}^{r} l_i)} \oplus_{i=1}^{n} k \rightarrow \prod SL_{d_0} \), with \( \tau = (\tau_1, \ldots, \tau_n) \)
so that \( L = \varphi(\prod_{i=1}^{r} H_i(l_i)) \subset H(k) \).

We now claim

\[
(6.27) \quad r = n.
\]

Assuming \([6,27]\), and after possibly renumbering and replacing \( l_i \) by \( \tau_i(l_i) \) for
\( 1 \leq i \leq r = n \), we get the proposition.

We now turn to the proof of \([6,27]\). Put \( \Delta := H(k) \cap \Gamma \) and recall the notation
\( A_H = A \cap g_0 H(k) g_0^{-1} \). In view of Lemma 6.13 we can reduce the study of the
measure \( \mu \) to the study of the measure \( \eta \), which is an \( A_H \)-ergodic invariant measure
on \( g_0 H(k)/\Delta \). Put

\[
H' := \mathcal{R} \oplus_{r=1}^{r} l_i \text{-group and } H' (\oplus_{i=1}^{r} l_i) = H(k), \text{ see } [6, \text{ Prop. A.5.2}].
\]

Moreover, \( L = \varphi(\prod_{i=1}^{r} H_i(l_i)) \) is the group of \( \oplus_{i=1}^{r} l_i \)-points of a \( \oplus_{i=1}^{r} l_i \)-subgroup
of \( H' \), see \([6, \text{ Prop. A.5.7}]\). Define

\[
(6.28) \quad R := \text{ the Zariski closure of } N_{H(k)}(L) \cap \Delta \text{ in } H';
\]
we note that the Zariski topology on \( H' \) is defined fiberwise. Put

\[
R = \mathcal{R} (\oplus_{i=1}^{r} l_i) \subset H(k).
\]

Then \( R \subset N_{H(k)}(L) \).

In view of \([6,19]\) and Lemma 6.13 we have the following. For \( \eta \text{-a.e. } x \in H(k)/\Delta \)
and \( \eta_p \text{-a.e. } z \) we have

\[
\text{supp}(\nu_z) = g_0 g L \Delta / \Delta
\]
for some \( g \in H(k) \).

Therefore, arguing for each \( i \) separately, as in the proof of Lemma 6.9 we get the following. There is a cocompact subgroup \( A_H' \subset A_H \) and some \( g_1 \in H(k) \) so that

\[
g_1^{-1} g_0^{-1} A_H g_0 g_1 \subset R,
\]

moreover, \( \text{supp}(\eta) = \text{supp}(\eta) \).

In particular we have \( A_H' \) normalizes the group \( g_0 g_1 L g_0^{-1} g_0^{-1} \). Recall now that
\( A_H \) is a maximal torus in the block diagonal group \( g_0 H(k) g_0^{-1} \). These and the fact
that \( A_H' \) is cocompact in \( A_H \) imply that the block structure of \( L \) and \( H \) agree
with each other, i.e. \( r = n \). To see this, assume \( i(j) = 1 \) for \( j = 1, 2 \). Let \( a \) be an
element in \( A_H' \) which equals the identity in all the blocks \( j = 2, \ldots, n \) and in the
first block it is a diagonal elements which generates an unbounded group. Then
since \( a \) normalizes \( g_0 g_1 L g_0^{-1} g_0^{-1} \) we get a contradiction.

Corollary 6.15. \( N_{H(k)}(L)/C(H(k))L \) is an abelian group.
Proof. In view of Proposition [6.14] it suffices to argue in each $\text{SL}_d$-block separately. Hence we fix some $i \in \{1, \ldots, n\}$. First note that $H_i$ is an $l_i$-form of $\text{SL}_d$. Suppose now that $g \in \text{SL}(d_0, k)$ normalises $H_i(l_i)$. Since $H_i(l_i)$ is Zariski dense in the $l_i$-group $H_i$, see e.g. [25] Ch. 1, Prop. 2.5.3, we thus get that $g$ induces an $l_i$-automorphism of $H_i$. Extending the scalars from $l_i$ to $k$ we see that the automorphism is inner, i.e. this automorphism $\sigma(g)$ belongs to $H_i^{ad}(k)$. Together it follows that $\sigma_i(g) \in H_i^{ad}(l_i)$. This automorphism is, moreover, nontrivial if and only if $g$ is not central in $\text{SL}_d$.

Hence, we get a monomorphism $g \mapsto \sigma(g)$ from $N_{\text{SL}(d_0, k)}(L)/C(\text{SL}(d_0, k))$ into $H_i^{ad}(l_i)$. This map sends $H_i(l_i)$ to $[H_i^{ad}(l_i), H_i^{ad}(l_i)]$ by [25] Ch. 1, Thm. 2.3.1. The claim thus follows.

Let us now complete the proof of Theorem [1.1].

Proof of Theorem [1.1]. In view of Lemma [6.13] we may and will restrict our attention to the measure $\eta$ appearing in the statement of that lemma. Similar to the proof of (6.27), put $\Delta := H(k) \cap \Gamma$. Define

$$H' := \mathcal{R}_{\oplus_{i=1}^n k/\oplus_{i=1}^n l_i}(\prod_{i=1}^n \text{SL}_d).$$

Then $H'$ is a smooth $\oplus_{i=1}^n l_i$-group and $H'(\oplus_{i=1}^n l_i) = H(k)$, see [6] Prop. A.5.2. Moreover, $L = \prod_{i=1}^n H_i(l_i)$ is the group of $\oplus_{i=1}^n l_i$-points of a $\oplus_{i=1}^n l_i$-subgroup of $H'$, see [6] Prop. A.5.7. Define

$$R := C(H(k))(\text{the Zariski closure of } N_{H(k)}(L) \cap \Delta \text{ in } H').$$

Put $R = \mathcal{R}(\oplus_{i=1}^n l_i) \subset H(k)$, since $H(k) = H'(\oplus_{i=1}^n l_i)$ we have $C(H(k)) \subset R$. Moreover, $R \subset N_{H(k)}(L)$, and by Corollary [6.15] we have

(6.29) $[R, R] \subset C(H(k))L$.

In view of (6.19) and Lemma [6.13] for $\eta$-a.e. $x \in g_0 H(k)/\Delta$ we have

(6.30) $\text{supp}(\nu_x) = g_0 g L \Delta / \Delta$

for some $g \in H(k)$.

Therefore, arguing as in the proof of Lemma [6.9] we get the following. There is a cocompact subgroup $A'^{\#}_{H} \subset A_H$ and some $g_1 \in H(k)$ so that $g_1^{-1} g_0^{-1} A'^{\#}_{H} g_0 g_1 \subset R$, moreover $\overline{A_H g_0 g_1 \Gamma / \Gamma} = \text{supp}(\eta)$. We note that we may and will assume that

$$C(H(k)) \subset A'^{\#}_{H}.$$

This gives the following decomposition.

(6.31) $\eta = \int_{A_H/A'^{\#}_{H}} a \cdot \eta' \, da$,

where

- $da$ is the Haar measure on the compact group $A_H/A'^{\#}_{H}$,
- $\eta'$ is an $A'^{\#}_{H}$-invariant, ergodic, probability measure on $g_0 g_1 R / R \cap \Delta$.

We now further investigate the measure $\eta'$. In view of (6.30) we can write

(6.32) $\eta' = \int \nu_x \, d\eta'(x)$,
where \( \nu_x \) is the \( g_0 g_1 g L g^{-1} g_1^{-1} g_0^{-1} \)-invariant measure on \( g_0 g_1 g L \Delta / \Delta \) for \( \eta' \)-a.e. \( x \). Since \( L \) is normal in \( R \), we get that \( \eta' \) is \( g_0 g_1 g L g^{-1} g_1^{-1} g_0^{-1} \)-invariant. Moreover, since \( C(H(k)) \subset A^1_H \), we also have \( \eta' \) is \( C(H(k)) \)-invariant. Finally since \( L \Delta / \Delta \) is closed in \( H(k) / \Delta \) we have \( C(H(k)) L (R \cap \Delta) \) is closed subgroup of \( R \), see (6.29).

By (6.32) we obtain
\[
\eta' = \int_{g_0 g_1 R / L (R \cap \Delta)} \eta'_L \, d\eta'(g \Delta)
= \int_{g_0 g_1 R / C(H(k)) L (R \cap \Delta)} \int_{C(H(k))} h_* \nu_L \, dh \, d\eta'(g \Delta).
\]

Here the outer integral is essentially over the abelian group
\[ P = R / C(H(k)) L (R \cap \Delta) \]
with respect to an \( A^1_H \)-invariant and ergodic probability measure. This implies that the image of \( A^1_H \) in \( P \) is compact and the measure equals the Haar measure on a coset of \( A^1_H / C(H(k)) L (R \cap \Delta) \). This, (6.31) and Lemma 6.13 finish the proof. \( \square \)

7. Joining classification

7.1. On the group generated by certain commutators. A key to the classification of joinings is the following simple general fact about a rank two \( k \)-torus. Let \( G \) denotes a connected, simply connected, absolutely almost simple group defined over a local field \( k \) with \( \text{char}(k) > 3 \). Let \( \lambda : G^2_{m} \to G \) be an algebraic monomorphism defined over \( k \); let \( A = \lambda(G^2_{m}) \). Fix a maximal \( k \)-split, \( k \)-torus \( \mathbf{S} \subset G \) so that \( A \subset \mathbf{S} \). Further, let \( \mathbf{T} \supset \mathbf{S} \) be a maximal torus of \( G \) which is defined over \( k \). Put \( \Phi := \Phi(T, G) \), \( _k \Phi := _k \Phi(S, G) \), and \( \Phi := _k \Phi(A, G) \). For \( \Psi \subset \Phi \) set
\[
\Psi(T, G) := \{ \alpha \in \Phi(T, G) : \alpha|A \in \Psi \}.
\]

Proposition 7.1. The group \( G \) is generated by the commutators \([V_{\alpha}, V_{\beta}]\) where \( \alpha, \beta \) run over all linearly independent pairs in \( \Phi \).

We need the following lemma from [12, Lemma 4.2], see also [9, Lemma 9.6].

Lemma 7.2. Let \( \delta \in \Phi \) and \( \delta' \in \delta(\delta') \). Then there exist some \( \beta \in \Phi \) and some \( \beta' \in \delta(\delta') \) with the following properties.

1. \( \{ \beta, \delta \} \) is a linearly independent subset of \( \Phi \).
2. \( \delta' - \beta' \in \Phi \).

Proof. Let \( \bar{k} \) be the algebraic closure of \( k \). Let
\[
\Upsilon = \{ \alpha \in \mathbb{R} \otimes X^* (T) : \alpha|_A \in \mathbb{R} \delta \},
\]
where \( X^* (T) \) denotes the group of characters of \( T \).

Let \( g' \) be the \( \bar{k} \)-span of \( \{ g_{\alpha'}, [g_{\alpha'}, g_{\beta'}] : \alpha', \beta' \in \Phi \setminus T \} \). It follows easily from the Jacobi identity (cf. the proof of [12, Lemma 4.2] for details) that \( g' \) is an ideal of \( g \). Recall that \( A = \lambda(G^2_{m}) \). Therefore, \( \Phi \) has at least two linearly independent roots, and \( g' \) is not central. Since \( g \) has no proper non-central ideals, we have \( g' = g \).

In particular, we get that
\[
g_{\delta'} \subset \sum_{\alpha' \in \Phi \setminus T} g_{\alpha'} + \sum_{\alpha', \beta' \in \Phi \setminus T} [g_{\alpha'}, g_{\beta'}].
\]
Since $\delta' \in \mathcal{Y}$, the above implies that $g_{\delta'} \subset \sum_{\alpha', \beta' \in \Phi} [g_{\alpha'}, g_{\beta'}]$. But for every $\alpha', \beta'$, we have that $[g_{\alpha'}, g_{\beta'}] \subset g_{\alpha'+\beta'}$ hence $\delta' = \alpha' + \beta'$ for some $\alpha', \beta' \in \Phi \setminus \mathcal{Y}$. In particular, since $\beta' \notin \mathcal{Y}$, it holds that $\beta := \beta'|_A$ is linearly independent from $\delta$. □

**Proof of Proposition 7.1.** Since the statement of the proposition is on the level of algebraic groups, the validity of the statement over the algebraic closure $\overline{k}$ of $k$ implies that of the statement when the groups are considered as algebraic groups over $k$. Over $\overline{k}$, we can write for every $\alpha \in \overline{\Phi}$

$$V_{\alpha} = \prod_{\delta \in \delta(\alpha)} U_{\delta'}$$

with each $U_{\delta'}$ a one parameter unipotent group over $\overline{k}$.

Since the group $G$ is absolutely almost simple, in particular semisimple, the root groups $U_{\delta'}$ for $\delta' \in \Phi$ generate. Therefore to prove the proposition it is enough to show that for every $\delta' \in \Phi$, one can find $\alpha$ and $\beta$ in $\overline{\Phi}$, linearly independent, so that

$$U_{\delta'} \subset [V_{\alpha}, V_{\beta}].$$

Let $\beta, \beta'$ be as in Lemma 7.2 applied to $\delta := \delta'|_{A_1}$ and $\delta'$, and let $\alpha' = \delta' - \beta'$ and $\alpha = \alpha'|_{A}$. In particular, $\alpha$ and $\beta$ are linearly independent.

Recall that $\text{char}(k) \neq 2, 3$, hence by [4, §4.3] irregular commutation relations do not occur. This means in particular that

$$[U_{\alpha'}, U_{\beta}] = U_{\alpha'+\beta'}$$

(cf. also [3, §2.5]). But $U_{\alpha'} \subset V_{\alpha}, U_{\beta} \subset V_{\beta}$, and by definition $\alpha' + \beta' = \delta'$. Equation (7.2) and hence the proposition follows. □

### 7.2. The main entropy inequality and the invariance group of the leafwise measures.

From now on, we use the notation from Theorem 1.2. In particular, for $i = 1, 2$, $G_i$ denotes a connected, simply connected, absolutely almost simple group defined over $k$. We put $G_i = G_i(k)$ and $G = G_1 \times G_2$. Recall also that $\text{char}(k) \geq 3$.

Suppose fixed two algebraic monomorphisms $\lambda_i : G_m^2 \to G_i$ defined over $k$; let $A_i = \lambda_i(G_m^2)$ and $A_i = A_i(k)$. For $i = 1, 2$ we fix a maximal $k$-split, $k$-torus $S_i \subset G_i$ so that $A_i \subset S_i$, and set $\Phi_i := k\Phi(S_i, G_i)$, and $\overline{\Phi}_i := k\Phi(A_i, G_i)$.

Define

$$A := \{(\lambda_1(r), \lambda_2(r)) : r \in G_m^2\}$$

and let $A := A(k)$.

Let

$$\overline{\Phi} = k\Phi(A, G_1 \times G_2).$$

Using the natural homomorphisms from $A$ to $A_i$, for $i = 1, 2$ we can view $k\Phi(A_i, G_i)$ as subsets of $\overline{\Phi}$ and moreover we have that

$$\overline{\Phi} = k\Phi(A_1, G_1) \cup k\Phi(A_2, G_2).$$

For each $\alpha \in \overline{\Phi}$, we can write the coarse Lyapunov group $V_{\alpha} \subset G_1 \times G_2$ as a product $V_{\alpha}^i \times V_{\alpha}^{i'}$, with $V_{\alpha}^i \subset G_i$; by convention if $\alpha \notin \overline{\Phi}$ then $V_{\alpha}^i = \{1\}$. For $i = 1, 2$ we fix a maximal, compact, open subgroup $\mathcal{G}_i \subset G_i$ and put $\mathfrak{G}_i := \mathcal{G}_i \times \mathcal{G}_j$.

Recall that $\mu$ denotes an ergodic joining for the action of $A_i$ on $(X_i, m_i)$ for $i = 1, 2$. 

Corollary 7.3. For any \( \Phi \) is a (Zariski closed) subgroup which is normalized by \( h \). Put

\[
W = V_{\Phi} \subset W_{G_1 \times G_2}(a).
\]

Then \( W = W_1 \times W_2 \) where \( W_i \subset G_i \) for \( i = 1, 2 \) and

\[
(7.3) \quad h_\mu(a, W) \leq h_{m_1}(a, W_1) + h_\mu(a, \{\text{id}\} \times W_2).
\]

Furthermore, the following hold.

1. If the equality holds in \( (7.3) \), then \( W_1 \) is the smallest algebraic subgroup of \( W \) which contains \( \pi_1(\text{supp}(\mu^W) \cap \Theta) \).
2. The equality holds for \( W = W_{G_1 \times G_2}(a) \).
3. For every \( \alpha \in \Phi \), the equality holds for \( W = V_{[\alpha]} \).

Proof. The main inequality follows from \( 12 \) Prop. 3.1.

Parts (2) and (3) follow from \( 12 \) Prop. 3.3 and Cor. 3.4.

To see part (1), first note that by \( 13 \), Prop. 6.2 we have

\[
\pi_1\left(\text{supp}(\mu^W) \cap \Theta^z\right)
\]

is a (Zariski closed) subgroup which is normalized by \( a \) and contains \( \pi_1(\text{supp}(\mu^W)) \).

Part (1) now follows from \( 12 \) Prop. 3.2.

Corollary 7.3. For any \( \alpha \in \Phi \), we have that \( \pi_i(\mathcal{S}^{[\alpha]}_x \cap \Theta) \) is Zariski dense in \( \pi_i(V_{[\alpha]}) \) for \( i = 1, 2 \).

Proof. In view of Proposition 7.2 (3), this is a direct consequence of Proposition 7.2 (1) and the definition of \( \mathcal{S}^{[\alpha]}_x \).

Fix an element \( a = (a_1, a_2) \in A \) that is regular with respect to \( \Phi \), that is: \( \alpha(a) \neq 1 \) for any \( \alpha \in \Phi \). We denote the Pinsker \( \sigma \)-algebra, \( \mathcal{P}_a \), simply by \( \mathcal{P} \).

Disintegrate \( \mu \) as follows.

\[
(7.4) \quad \mu = \int_X \mu^P_x \, d\mu(x),
\]

where \( \mu^P_x \) denotes the \( \mathcal{P} \)-conditional measure for \( \mu \)-almost every \( x \in X \).

Similar to \( 6.5 \), define

\[
\mathcal{H}_x := \{g \in G_1 \times G_2 : g \mu^P_x = \mu^P_x\}.
\]

We have \( a \mathcal{H}_x a^{-1} = \mathcal{H}_x \) for all \( a \in A \) and \( \mu \)-a.e. \( x \), see \( 6.6 \).

Lemma 7.4. For \( \mu \)-a.e. \( x \), and any linearly independent \( \alpha, \beta \in \Phi \) the measure \( \mu^P_x \) is a.s. invariant under \( [\mathcal{S}^{[\alpha]}_x, \mathcal{S}^{[\beta]}_x] \), i.e. \( [\mathcal{S}^{[\alpha]}_x, \mathcal{S}^{[\beta]}_x] \subset \mathcal{H}_x \).

Proof. By Lemma 3.14 for every \( \alpha \in \Phi \) and \( \mu \)-a.e. \( x \), we have that \( \mu^P_x \) is invariant under \( I^{[\alpha]}_x \), and hence by Lemma 3.11 for any positively closed \( \Psi \subset \Phi \). By Lemma 3.14 we have therefore that for any linearly independent \( \alpha, \beta \in \Phi \) the measure \( \mu^P_x \) is a.s. invariant under \( [\mathcal{S}^{[\alpha]}_x, \mathcal{S}^{[\beta]}_x] \).

Recall that \( \Theta = \Theta_1 \times \Theta_2 \) is a compact, open subgroup of \( G = G_1 \times G_2 \). Define

\[
Q_x := \{g \in \mathcal{H}_x \cap \Theta : g \text{ is unipotent}\}.
\]

\footnote{The arguments in \( 12 \) generalize to the setting at hand without a change.}
Corollary 7.5. For \( \mu \)-a.e. \( x \), \( \pi_i(Q_x) \) is Zariski dense in \( G_i \) and \( \pi_i(H_x) \) is unbounded for \( i = 1, 2 \).

Proof. For any \( x \), let \( L_{i,x} \) denote the Zariski closure of \( \pi_i(Q_x) \) in \( G_i \). Let \( \alpha, \beta \in \mathcal{F} \) be two linearly independent roots. By Corollary 7.3 a.s. \( \pi_i(S_x^{[\alpha]} \cap \Theta) \) is Zariski dense in \( \pi_i(V_{[\alpha]}) \) and similarly for \( \beta \), for \( i = 1, 2 \). By Lemma 7.4 \( [S_x^{[\alpha]} \cap \Theta, S_x^{[\beta]} \cap \Theta] \subset Q_x \). It follows that

\[
\pi_i([V_{[\alpha]}, V_{[\beta]}]) \subset L_{i,x}
\]

for any two linearly independent \( \alpha, \beta \in \mathcal{F} \). The first part of the claim follows using Proposition 7.1.

For the second, by Lemma 7.4 and Lemma 3.12 there is an \( \alpha \in \mathcal{F} \) such that \( I_x^{[\alpha]} \) is non trivial. If \( I_x^{[\alpha]} \) would be bounded on a set of positive measure its diameter would be a monotone increasing measurable function under an appropriate subsemigroup of \( A \), in contradiction to Poincare recurrence. \( \square \)

7.3. Proof of Theorem 1.2 Let \( X' \subset X \) be a conull subset so that the conclusions of Lemma 3.5 and Corollary 7.5 hold true on \( X' \).

By Corollary 7.3, for all \( x \in X' \) the group \( Q_x \) satisfies the conditions in Theorem A.2 in Section 3.1. Therefore, there are two possibilities to consider.

Case 1: There is a subset \( X'' \subset X' \) with \( \mu(X'') > 0 \) so that for all \( x \in X'' \) and \( i = 1, 2 \), the following holds. There are

- subfields \( k_{i,x} \subset k \),
- \( k_{i,x} \) groups \( H_{i,x} \),
- \( k \)-isomorphism \( \varphi_{i,x} : H_{i,x} \times k_{i,x} \rightarrow G_i \), and
- open, compact subgroups \( Q_{i,x} \subset \varphi_{i,x}(H_{i,x}(k_{i,x})) \),

so that \( Q_{1,x} \times Q_{2,x} \subset Q_x \).

Lemma 7.6. For every \( x \in X'' \) and every \( h \in Q_{1,x} \) define

\[
F_x(h) := \{ v(h, 1)v^{-1} : v \in H_x \}.
\]

(1) For every \( h \in Q_{1,x} \) we have \( F_x(h) \subset H_x \).

(2) There exists an element \( h \in Q_{1,x} \) such that \( F_x(h) \) is unbounded.

Proof. Part (1) is immediate since \( Q_{1,x} \times \{ 1 \} \subset Q_x \).

We now prove part (2). Let \( \{ v_n \} \subset H_x \) be a sequence so that \( \pi_1(v_n) \rightarrow \infty \), see Corollary 7.5. Let

\[
v_n = (v_{n,1}, v_{n,2}) = (r_{n,1}s_{n,1}r_{n,1}, r_{n,2}s_{n,2}r_{n,2})
\]

be the Cartan decomposition of \( v_n \). Then \( s_{n,1} \rightarrow \infty \).

Passing to a subsequence, if necessary, we assume that

- \( \{ r_{n,i} \} \) and \( \{ r_{n,i}' \} \) converge for \( i = 1, 2 \), moreover,
- \( P := \{ g \in G_1 : s_{n,1}^{-1}gs_{n,1} = \text{ bounded} \} \) is a proper parabolic \( k \)-subgroup of \( G_1 \).

Since \( Q_{1,x} \) is Zariski density in the \( k \)-group \( G_1 \), there exists some \( h \in Q_{1,x} \) which does not lie in \( r^{-1}P r \) where \( r_{n,1} \rightarrow r \). The claim in part (2) holds for this \( h \). \( \square \)
Proof of Theorem 1.2: Case 1. Let \( x \in X'' \), and let \( h \) and \( F_x(h) \) be as in part (2) of Lemma 7.6. Suppose \( \{(g_n, 1)\} \subset F_x(h) \) is an unbounded sequence. By part (1) of that Lemma we have

\[
\pi \chi \pi = \chi \pi \quad \forall \chi \in \pi \chi \pi.
\]

Recall from Lemma 7.3 that

\[
\pi_{\chi \pi}(\mu^g) = m_i \quad \text{for } i = 1, 2.
\]

Since \( G_1 \) is connected, simply connected, and absolutely almost simple, it follows from the generalized Mautner phenomenon, [25, Ch. 1, Thm. 2.3.1, Ch. 2, Thm. 7.2], that \((X_1, m_1)\) is ergodic for the action of the unbounded group \((\{g_n\})\).

This together with (7.5) and (7.6) implies that \( \mu^g = m_1 \times m_2 \), see e.g. the argument in Case 1 of the proof of [10, Prop. 4.3].

Since \( \mu(X'') > 0 \) and \( \mu \) is \( A \)-ergodic, we get that \( \mu = m_1 \times m_2 \).

The rest of this section is devoted to the analysis of the following case.

Case 2: Replacing \( X' \) by a conull subset, which we continue to denote by \( X' \), we have the following. For every \( x \in X' \) there are

- a subfield \( k_x \subset k \) and a continuous embedding \( \tau_x : k_x \to k \),
- a \( k_x \)-group \( H_x \), and
- a \( k \oplus k \)-isomorphism \( \varphi_x : H_x \times \Delta_{\tau_x}(k_x)(k \oplus k) \to G_1 \coprod G_2 \) where as in (3.4), \( \Delta_{\tau_x}(k_x) = \{(c, \tau_x(c)) : c \in k_x\} \)

so that \( Q_x \) is an open subset of the image under \( \varphi_x \) of \( H_x(k_x) \) with the latter considered as a subset of the \( k \oplus k \)-points of \( H_x \times \Delta_{\tau_x}(k_x)(k \oplus k) \) using the injection of rings \( \Delta_{\tau_x} : k_x \to k \oplus k \). Moreover, \( \Delta_{\tau_x}(k_x) \) is unique, and \( H_x \) and \( \varphi_x \) are unique up to unique isomorphisms.

Let us further recall that

\[
k_x = \text{the field of quotients of the ring generated by } \{\text{tr}(\rho(g)) : g \in Q_x\},
\]

where \( \rho \) denotes the non-constant irreducible representation occurring as subquotient of the adjoint representation of \( G_1^{ad} \).

Put \( E_x := \varphi_x(H_x(k_x)) \subset G_1 \times G_2 \).

Proposition 7.7.

1. There is a subfield \( k' \subset k \) and an embedding \( \tau : k' \to k \) so that \( \Delta_{\tau}(k_x) = \Delta_{\tau}(k') \) on a conull subset of \( X \).
2. The map \( x \mapsto E_x \) is an \( A \)-equivariant Borel map on a conull subset of \( X \).

Proof. In view of (7.7) and the fact that \( x \mapsto Q_x \) is a Borel map, we get that \( x \mapsto \Delta_{\tau_x}(k_x) \) is a Borel map, see the proof of Lemma 6.3(1).

To see the other claims in part (1), first recall that \( aH_a^{-1} = H_{ax} \) for all \( a \in A \) and \( \mu \)-a.e. \( x \in X \). Hence, for any \( a \in A \) there exists some finite index subgroup \( Q_x(a) \subset Q_x \) so that

\[
aQ_x(a)a^{-1} \subset Q_{ax}.
\]

Therefore, the same arguments as in the proof of Lemma 6.6(1) applies here and finishes the proof of part (1), see (6.12) and (6.13).

We now turn to the proof of part (2). Put

\[
G' := \mathcal{R}_{k \oplus k / \Delta_{\tau}(k')} (G_1 \coprod G_2);
\]
This is a $\Delta_r(k')$-group.

Now, part (1), the fact that $\varphi_x$ is an isomorphism, and the universal property of the restriction of scalars functor, see [6, §A.5], imply that

$$E_x = \left( R_{k \oplus k/\Delta_r(k')} (\varphi_x) (H_x) \right) (\Delta_r(k')).$$

Hence, using [29] Ch. 1, Prop. 2.5.3, we get that $E_x$ is identified with the $\Delta_r(k')$-points of the Zariski closure of $Q_x$ in the $\Delta_r(k')$-group $G'$.

Since the map $x \mapsto Q_x$ is Borel, we thus get that $x \mapsto E_x$ is a Borel map.

To see the $A$-equivariance, first recall from (7.8) that $a Q_x (a)^{-1}$ is an open subgroup of $Q_{ax}$. Using [29] Ch. 1, Prop. 2.5.3, thus, we get that $E_{ax}$ is the Zariski closure of $a Q_x (a)^{-1}$ in $G' (\Delta_r(k'))$. On the other hand, this Zariski closure equals $a E_x a^{-1}$; the claim follows. □

**Lemma 7.8.** For $\mu$-a.e. $x \in X$ we have $E_x \subset \mathcal{H}_x$ and $E_x$ is not compact.

**Proof.** We first recall from [29] Thm. 1 that since $H_x$ is connected, simply connected, and absolutely almost simple, any open and unbounded subgroup of $E_x$ equals $E_x$. Since $Q_x \subset \mathcal{H}_x$ is an open subgroup of $E_x$, thus, both assertions in the lemma will follow if we show that $\mathcal{H}_x \cap E_x$ is unbounded for $\mu$-a.e. $x \in X$.

However, the proof of Corollary 7.5 shows that for some $\alpha \in \Phi$, we have that $Q_x \cap T^{[\alpha]}_x$ is non-trivial. Since $x \mapsto E_x$ is an $A$-equivariant map, using Poincare recurrence as in Corollary 7.5 it follows that $\mathcal{H}_x \cap E_x$ is unbounded. □

**Proof of Theorem 1.2, Case 2.** The argument is similar to the proof of Theorem 1.1

**Step 1.** Let

$$\mu_P^x = \int_X \nu_z \, d\mu_P^x (z)$$

be the ergodic decomposition of $\mu_P^x$ with respect to $E_x$.

As before, $k \oplus k$ is a $\Delta_r(k')$-algebra. Put

$$G' := R_{k \oplus k/\Delta_r(k')} \left( G_1 \coprod G_2 \right).$$

This is a connected group defined over $\Delta_r(k')$, [6, §A5]. Moreover, $\Gamma_1 \times \Gamma_2$ is a lattice in $G' (\Delta_r(k')) = G_1 (k) \times G_2 (k) = G_1 \times G_2 = G$.

Applying Theorem B in Section 3.2 we conclude that for $\mu_P^x$-a.e. $z$ the measure $\nu_z$ is described as follows. There exist

1. $l_z = (k')^{n_z}$ where $q_z = p^{n_z}$, $p = \text{char}(k)$, and $n_z \geq 1$,
2. a connected $\Delta_r(l_z)$-subgroup $M_z$ of $R_{\Delta_r(k')} / R_{\Delta_r(l_z)} (G')$ so that $M_z (\Delta_r(l_z)) \cap (\Gamma_1 \times \Gamma_2)$ is Zariski dense in $M_z$, and
3. an element $g_z \in G_1 \times G_2$,

such that $\nu_z$ is the $g_z L_z g_z^{-1}$-invariant probability Haar measure on the closed orbit $g_z L_z (\Gamma_1 \times \Gamma_2) / (\Gamma_1 \times \Gamma_2)$ with

$$L_z = M_z^+ (\lambda_z) (M_z (\Delta_r(l_z)) \cap (\Gamma_1 \times \Gamma_2))$$

where

- the closure is with respect to the Hausdorff topology, and
\[ \lambda_z : \mathbb{G}_m \to \mathbb{M}_z \] is a noncentral \( \Delta \)-homomorphism, \( M^+_z(\lambda_z) \) is defined in (3.9), and \( E_x \subset M^+_z(\lambda_z) \).

Arguing as in the proof of Lemma 6.8, there exists a triple \( (l_0, [M_0], [M_0^+(\lambda_0)]) \) so that

\[ (l_0, [M_z], [M_z^+(\lambda_z)]) = (l_0, [M_0], [M_0^+(\lambda_0)]) \] for \( \mu \)-a.e. \( x \) and \( \mu^+_x \)-a.e. \( z \).

Put \( L_0 := M_0^+(\lambda_0)([M_0](\Delta l_0)) \cap (\Gamma_1 \times \Gamma_2) \).

Step 2. One of the following holds

(a) \( L_0 = G_1 \times G_2 \), or

(b) \( \pi_i(L_0) = G_i \) and \( \ker(\pi_i|_{L_0}) \subset C(G_1 \times G_2) \) for \( i = 1, 2 \).

To see this, first note that by Lemma 3.5 we have \( \pi_i \mu^+_x = m_i \) for \( \mu \)-a.e. \( x \in X \) and \( i = 1, 2 \). This, together with (7.9), implies that

\[ m_i = \pi_i \mu^+_x = \int_X \pi_i \nu_x \, d\mu^+_x(z) \] for \( \mu \)-a.e. \( x \).

Since \( \nu_x \) is invariant under \( E_x \), the projection \( \pi_i(\nu_x) \) is invariant under \( \pi_i(E_x) \).

By Lemma 7.8 the group \( \pi_i(E_x) \) is an unbounded subgroup of \( G_i \) for \( i = 1, 2 \).

Since \( G_i \) is simply connected, \( m_i \) is \( \pi_i(E_x) \) ergodic, see [25] Ch. 1, Thm. 2.3.1, Ch. 2, Thm. 7.2]. Therefore,

\[ \pi_i \nu_x = m_i \] for \( \mu^+_x \)-a.e. \( z \).

In particular, we get that \( \pi_i(g \cdot L_0 g^{-1}) = G_i \) for \( \mu^+_x \)-a.e. \( z \) and \( i = 1, 2 \).

Since \( G_i \) is absolutely almost simple, any proper normal subgroup of \( G_i \), as an abstract group, is central [25] Ch. 1, Thm. 1.5.6]. This implies that one of the following holds.

- \( L_0 = G_1 \times G_2 \), or

- \( \pi_i(L_0) = G_i \) and \( \ker(\pi_i|_{L_0}) \subset C(G_1 \times G_2) \) for \( i = 1, 2 \).

as we claimed.

If \( L_0 = G \times G \), we are done with the proof. Hence, our standing assumption for the rest of the argument is that (b) above holds.

Step 3. The assertion in (b) also holds for \( M_0 \) and \( M_0^+(\lambda_0) \) in place of \( L_0 \).

Let us first show this for \( M_0 \). Since \( L_0 \subset M_0 \) we have

\[ \pi_i(M_0) = G_i \] for \( i = 1, 2 \).

Therefore, as above, either \( M_0 = G_1 \times G_2 \) or (b) holds for \( M_0 \). Assume to the contrary that \( M_0 = G_1 \times G_2 \). Recall that \( \lambda_0 : \mathbb{G}_m \to \mathbb{M}_0 \) is a noncentral homomorphism. Since \( G_i \) is connected, simply connected, and absolutely almost simple for \( i = 1, 2 \), using [25] Ch. 1, Prop. 1.5.4 and Thm. 2.3.1], we have that either

- \( M_0^+ \lambda_0 = G_1 \times G_2 \), or

- \( M_0^+ \lambda_0 \subset G_i \) for some \( i = 1, 2 \).

However, since \( M_0^+(\lambda_0) \subset L_0 \), the above contradict our assumption that (b) holds.

We now turn to the proof of the claim for \( M_0^+(\lambda_0) \). Since \( M_0 \neq G_1 \times G_2 \) and \( M_0^+(\lambda_0) \subset M_0 \), the claim follows if we show that

\[ \pi_i(M_0^+(\lambda_0)) = G_i \] for \( i = 1, 2 \).

To see this note that \( \lambda_0(l_0) \subset M_0(\lambda_0) \). Since (b) holds for \( M_0 \), we have \( \pi_i(\lambda_0(l_0)) \) is unbounded for \( i = 1, 2 \). Therefore, (7.10) follows from [25] Ch. 1, Prop. 1.5.4 and Thm. 2.3.1].
Let us record the following corollaries of the above discussion for later use. Since (b) holds for $M_0^+(\lambda_0)$, $L_0$, and $M_0$, we have

$$N_{G_1 \times G_2}(M_0) \subset CM_0$$

where $C := C(G_1 \times G_2)$

We also have

$$M_0^+(\lambda_0)$$

is a finite index subgroup of $L_0$ and of $M_0$.

**Step 4.** Both

$$M_0^+(\lambda_0)(\Gamma_1 \times \Gamma_2)/(\Gamma_1 \times \Gamma_2)$$

and

$$M_0(\Gamma_1 \times \Gamma_2)/(\Gamma_1 \times \Gamma_2)$$

are closed orbits with probability, invariant, Haar measures. In particular, $\nu_x$ is the Haar measure on the closed orbit

$$g_xM_0^+(\lambda_0)(\Gamma_1 \times \Gamma_2)/(\Gamma_1 \times \Gamma_2).$$

Indeed, let $\Lambda := M_0 \cap (\Gamma_1 \times \Gamma_2)$. Then by (7.12) and Step 1., $\Lambda$ is a lattice in $M_0$, as was claimed for $M_0$.

Using (7.12), once more, we have $\Lambda \cap M_0^+(\lambda_0)$ has finite index in $\Lambda$. This implies that $\Lambda \cap M_0^+(\lambda_0)$ is a lattice in $M_0^+(\lambda_0)$, hence, the claim for $M^+(\lambda_0)$.

**Step 5.** We are now in a position to finish the proof. In view of (7.11), (7.12) and Step 4., we can argue as in the proof of Lemma 6.9, see in particular (6.20), and get the following. Let $C' := C \cap (\Gamma_1 \times \Gamma_2)$. The decomposition

$$\mu = \int \nu_x \, d\mu$$

yields the Borel map $f(x) = g_xC'M_0$ from a conull subset of $X$ to $G_1 \times G_2/C'M_0$. Moreover, $f$ is an $A$-equivariant map.

Hence, it follows from Lemma 3.3 that there exists some

$$g_0 \in \text{Fix}_A(G_1 \times G_2/C'M_0)$$

so that $f_*\mu$ is the $A$-invariant measure on the compact orbit $Ag_0$.

By Lemma 3.2 and (7.12) we have $M_0^+(\lambda_0)$ is a normal and finite index subgroup of $M_0$; furthermore, $C'$ is a finite group. Therefore, arguing as we did to complete the proof Theorem 1.1 after (6.32), we get that there is some $g_1 \in M_0$ so that

$$\mu = \int_{A/A \cap g_0g_1M_0^+(\lambda_0)g_0^{-1}g_1^{-1}} a_*\nu \, da$$

where $da$ is the probability Haar measure on the compact group

$$A/A \cap g_0g_1M_0^+(\lambda_0)g_0^{-1}g_1^{-1},$$

and $\nu$ is the is the probability Haar measure on the closed orbit

$$g_0g_1M_0^+(\lambda_0)(\Gamma_1 \times \Gamma_2)/(\Gamma_1 \times \Gamma_2).$$

Hence, Theorem 1.2(2) holds with $\Sigma = g_0g_1M_0^+(\lambda_0)g_0^{-1}g_1^{-1}$. $\square$
