RAMSEY'S THEOREM FOR n-PARAMETER SETS

BY

R. L. GRAHAM AND B. L. ROTHSCHILD(1)

Dedicated to the memory of Jon Hal Folkman (1938–1969)

Abstract. Classes of objects called n-parameter sets are defined. A Ramsey theorem is proved to the effect that any partitioning into r classes of the k-parameter subsets of any sufficiently large n-parameter set must result in some l-parameter subset with all its k-parameter subsets in one class. Among the immediate corollaries are the lower dimensional cases of a Ramsey theorem for finite vector spaces (a conjecture of Rota), the theorem of van der Waerden on arithmetic progressions, a set theoretic generalization of a theorem of Schur, and Ramsey's Theorem itself.

1. Introduction. In 1930, F. P. Ramsey [10], [12] proved the following theorem:

THEOREM [RAMSEY]. Let k, l, r be positive integers. Then there is a number N = N(k, l, r), depending only on k, l and r, with the following property: If S is a set with at least N elements, and if all the subsets of S with k elements are divided into r classes in any way, then there is some subset of l elements with all of its subsets of k elements in a single class.

Since this theorem appeared there has been interest in finding generalizations, applications and analogues of it. The work presented here was motivated by a conjecture made by Gian-Carlo Rota, a geometric analogue to Ramsey's Theorem, which can be stated as follows:

CONJECTURE [ROTA]. Let l, k, r be nonnegative integers, and F a field of q elements. Then there is a number N = N(q, r, l, k) depending only on q, r, l and k with the following property: If V is a vector space over F of dimension at least N, and if all the k-dimensional subspaces of V are divided into r classes in any way, then there is some l-dimensional subspace with all of its k-dimensional subspaces in a single class.

This conjecture is obtained from the statement of Ramsey's Theorem essentially by replacing the notions of set and cardinality by those of vector space and dimension, respectively. If we replace the notion of vector space with that of affine space, then we obtain another conjecture. This conjecture is actually equivalent to Rota's conjecture [3], [11]. In this paper we prove another analogue to Ramsey's Theorem, in which we replace the notion of n-dimensional affine space by the

notion of $n$-parameter set, which we define later. The $n$-parameter sets are similar to $n$-dimensional affine spaces in certain ways, and, in fact, by appropriate choice of certain variables we can obtain results for vector and affine spaces. In particular, the affine conjecture is shown to be true for the cases of $k=0$ and $k=1$, with any choice for $l$, $r$ and $q$. This implies that Rota’s conjecture is true for $k=1$ and $k=2$ [3], [11]. Some other interesting results which follow from the $n$-parameter set analogue are presented as corollaries to the main result.

All of these analogues to Ramsey’s Theorem are just statements about some special kinds of subsets of certain sets and their inclusion relationships. Ramsey’s Theorem itself can be thought of thus as a statement about the lattices of subsets of finite sets; Rota’s conjecture refers to the lattices of subspaces of finite vector spaces; the affine analogue concerns the partially ordered sets of the subspaces of finite affine spaces. So also is the $n$-parameter set analogue a statement about partially ordered sets of special subsets of certain sets. We give here an informal description of $n$-parameter sets which may prove useful to the reader as motivation for the somewhat technical formal definition given in the next section.

Basically, just as $n$-dimensional affine space, as a set, consists of all $q^n$ $n$-tuples of elements from $GF(q)$, so an $n$-parameter set essentially consists of all $r^n$ $r$-tuples of elements of a set $A$ with $r$ elements, $A=\{a_1, \ldots, a_r\}$. Any 1-dimensional affine subspace of an affine $n$-space over $GF(q)$ consists of a set of $q$ $n$-tuples which can be written in a column as

$$(x_{11}, \ldots, x_{1n})$$
$$(x_{21}, \ldots, x_{2n})$$
$$\vdots$$
$$(x_{q1}, \ldots, x_{qn})$$

where for each $i$, $1 \leq i \leq n$, either $x_{1i}=x_{2i}=\ldots=x_{qi}$ or else $x_{1i}, \ldots, x_{qi}$ is a permutation of the elements $f_{1i}, \ldots, f_{qi}$ constituting $GF(q)$. The permutations obtainable in this way constitute a subset $L$ of all the $q!$ possible permutations. In a similar way, then, we define a 1-parameter subset of $A^n$ (the $n$-tuples of elements of $A$) as any set of $r$ $n$-tuples which can be listed

$$(a_{11}, \ldots, a_{1n})$$
$$\vdots$$
$$(a_{t1}, \ldots, a_{tn})$$

such that for each $i$, $1 \leq i \leq n$, either $a_{1i}=\ldots=a_{ti} \in B \subseteq A$, or else $a_{1i}, \ldots, a_{ti}$ is one of a certain set $L_{ii}$ of permutations of $a_{1i}, \ldots, a_i$ (the set of permutations considered is defined by a group $H$).

The general idea for $k$-parameter subsets can be illustrated by considering the case $k=2$. If $A_2$ is any 2-dimensional affine subspace of $GF(q)^n$, then $A_2=\{(x_1, \ldots, x_n)+\alpha(y_1, \ldots, y_n)+\beta(z_1, \ldots, z_n) : \alpha, \beta \in GF(q)\}$, where $x=(x_1, \ldots, x_n)$, $y=(y_1, \ldots, y_n)$, $z=(z_1, \ldots, z_n)$ are in $GF(q)^n$, $y, z\neq 0$, and addition and scalar
multiplication are defined as usual. If it happens that \( y_i z_i = 0 \) for \( i = 1, 2, \ldots, n \) (this is a relatively rare event), then we can partition the \( n \) coordinates into three disjoint sets: the coordinates \( i \) where \( z_i = 0 \) but \( y_i \neq 0 \), those where \( z_i \neq 0 \) but \( y_i = 0 \), and those where \( z_i = y_i = 0 \). Call these sets \( S_1 \), \( S_2 \) and \( S_0 \) respectively, and let

\[
S_1 = \{i_1, \ldots, i_{n_1}\}, \quad S_2 = \{j_1, \ldots, j_{n_2}\}, \quad S_0 = \{k_1, \ldots, k_{n_0}\}.
\]

If \( v = (v_1, \ldots, v_n) \in A_n \) then there are only \( q \) possibilities for \( (v_{i_1}, \ldots, v_{i_{n_1}}) \), \( q \) possibilities for \( (v_{j_1}, \ldots, v_{j_{n_2}}) \), and one possibility for \( (v_{k_1}, \ldots, v_{k_{n_0}}) \). Hence \( A_n \) can be formed precisely by listing the \( q \) values for each of \( S_1 \) and \( S_2 \) and the one from \( S_0 \) \( q \) times, and then selecting one from each of the lists in all \( q^2 \) possible ways:

\[
\begin{align*}
S_0 & \quad S_1 & \quad S_2 \\
(x_{k_1}, \ldots, x_{k_{n_0}}) & (y_{i_1}, \ldots, y_{i_{n_1}}) & (z_{1_{i_1}}, \ldots, z_{1_{i_{n_2}}}) \\
\vdots & \vdots & \vdots \\
(x_{k_1}, \ldots, x_{k_{n_0}}) & (y_{q_1}, \ldots, y_{q_{n_1}}) & (z_{q_{1_{i_1}}, \ldots, z_{q_{1_{i_{n_2}}}}})
\end{align*}
\]

The possible columns \( (y_{i_1}, \ldots, y_{q_{1_{1_{i_1}}}}) \) and \( (z_{1_{i_1}}, \ldots, z_{q_{1_{1_{i_1}}}}) \) are just the same as the set \( L \) of permutations in the 1-dimensional case above.

2-parameter sets, then, are described in a similar way. For a set \( A \) and a subset \( L_H \) of the permutations of \( A \), we form a 2-parameter subset of \( A^n \) as follows: First partition the set \( \{1, \ldots, n\} \) into three disjoint subsets \( S_0, S_1, S_2 \), with \( S_1 \) and \( S_2 \) nonempty. Then write three lists

\[
\begin{align*}
S_0 & \quad S_1 & \quad S_2 \\
(a, \ldots, b) & (x, \ldots, x') & (z, \ldots, z') \\
\vdots & \vdots & \vdots \\
(a, \ldots, b) & (y, \ldots, y') & (w, \ldots, w')
\end{align*}
\]

such that the columns under \( S_1 \) and \( S_2 \) are in \( L_H \). Finally, all \( t^2 \) elements of the 2-parameter subset are obtained by taking one entry (row) from each list.

To get \( k \)-parameter subsets we do the same thing with partitions into \( k+1 \) subsets \( S_0, \ldots, S_k \). For \( k \geq 2 \), these correspond to special affine subspaces of \( GF(q)^n \) but not to all of them. Thus the theorems we prove for \( n \)-parameter sets will not apply to all subspaces, as we would like, but only to some of them. For \( k = 0 \) and 1, however, we do prove results for all subspaces. These are considered later in the section on corollaries.

2. Definition of \( k \)-parameter set. In this section we formally define a \( k \)-parameter set. The reader might find it useful here to inspect the corollaries at the end of the paper. The examples of \( k \)-parameter sets there illustrate the definition.

Let \( A = \{a_1, a_2, \ldots, a_t\} \) be a finite set with \( t \geq 2 \). Let \( H : A \rightarrow A \) be a permutation group acting on \( A \). For \( a \in A \), \( \sigma \in H \), the action is denoted by \( a \rightarrow a^\sigma \). Also, for \( \sigma_1, \sigma_2 \in H \), \( \sigma_1 \sigma_2 \) is defined by \( a^{\sigma_1 \sigma_2} = (a^{\sigma_1})^{\sigma_2} \) for all \( a \in A \). For a nonempty
subset \( B \subseteq A \), let \( \bar{B} = \{ b : b \in B \} \) be the set of constant maps of \( A \) into \( A \) given by \( x^b = b \) for \( x \in A \), \( b \in \bar{B} \). \( A^t \) denotes the cartesian product \( A \times A \times \cdots \times A \) (\( t \) factors), which is just \( \{(x_1, \ldots, x_t) : x_i \in A, 1 \leq i \leq t\} \).

For \( x = (x_1, \ldots, x_t) \in A^t \), \( \sigma \in H \), we define an action of \( H : A^t \rightarrow A^t \) by
\[
x^\sigma = (x_1, \ldots, x_t)^\sigma = (x_1^\sigma, \ldots, x_t^\sigma) \in A^t.
\]
Similarly \( \bar{B} \) acts on \( A^t \) by
\[
x^b = (x_1, \ldots, x_t)^b = (x_1^b, \ldots, x_t^b) = (b, \ldots, b) \in A^t
\]
for \( x \in A^t \), \( b \in \bar{B} \).

For fixed integers \( n > 0 \) and \( 0 \leq k \leq n \), let \( \Pi = \{S_0, S_1, \ldots, S_k\} \) be a partition of the set \( I_n = \{1, 2, \ldots, n\} \) with \( S_i \neq \emptyset \) for \( 1 \leq i \leq k \). \( S_0 = \emptyset \) is possible. Let \( f : I_n \rightarrow H \cup \bar{B} \) be a mapping with the property:
\[
\begin{align*}
f(i) & \in \bar{B} \quad \text{if} \ i \in S_0, \\
f(i) & \in H \quad \text{if} \ i \in I_n - S_0.
\end{align*}
\]

The set \( P(A, \bar{B}, H, \Pi, f, n, k) = P \) is defined by
\[
P = \bigcup_{i \leq i_0, \ldots, i_k \leq i} \{(x_1, \ldots, x_n) : x_j = a_{i_j}^{(i_j)} \text{ if } j \in S_{i_j} \} \subseteq A^n.
\]

**Definition 1.** A subset \( P \subseteq A^n \) is said to be a \( k \)-parameter set in \( A^n \) if \( P = P(A, \bar{B}, H, \Pi, f, n, k) \) for some meaningful choice of these variables.

Let us consider this definition in more detail. We can write \( \Pi \) symbolically as follows:

\[
\begin{array}{c|c|c|c}
S_0 & S_1 & \cdots & S_k \\
\hline
\bar{a} \cdot \bar{b} & \pi_1 \cdots \delta_1 & \cdots & \pi_k \cdots \delta_k
\end{array}
\]

We imagine that we have bunched together the elements in the blocks of the partition \( \Pi \). With each \( i \in I_n \) we associate an element \( f(i) \in \bar{B} \cup H \). We can write this as
\[
\begin{array}{c|c|c|c}
S_0 & S_1 & \cdots & S_k \\
\hline
\bar{a} \cdot \bar{b} & \pi_1 \cdots \delta_1 & \cdots & \pi_k \cdots \delta_k
\end{array}
\]
where \( \bar{a}, \ldots, \bar{b} \in \bar{B}, \pi_1, \ldots, \delta_1, \ldots, \pi_k, \ldots, \delta_k \in H \). Define \( l_0 \) by
\[
l_0 = \begin{bmatrix}
a_1 \\
a_2 \\
\vdots \\
a_n
\end{bmatrix} \in A^t.
\]

We occasionally write elements of \( A^t \) as column vectors when this is useful for our purposes. The preceding is shorthand notation for
\[
\begin{array}{c|c|c|c}
S_0 & S_1 & \cdots & S_k \\
\hline
[l_0^1 \cdots l_0^n] & [l_0^1 \cdots l_0^n] & \cdots & [l_0^1 \cdots l_0^n]
\end{array},
\]

\( l_0 \).
which we can write as

\[
\begin{bmatrix}
S_0 & S_1 & S_k \\
\begin{bmatrix}
a_1^1 & \cdots & a_1^l & a_1^{l+1} & \cdots & a_1^k \\
a_2^1 & \cdots & a_2^l & a_2^{l+1} & \cdots & a_2^k \\
\vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\
a_i^1 & \cdots & a_i^l & a_i^{l+1} & \cdots & a_i^k
\end{bmatrix}
\end{bmatrix}
\]

which, of course, is just

\[
\begin{bmatrix}
S_0 & S_1 & S_k \\
\begin{bmatrix}
a & \cdots & b & a_1^{l+1} & \cdots & a_1^k \\
a & \cdots & b & a_2^{l+1} & \cdots & a_2^k \\
\vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\
a & \cdots & b & a_i^{l+1} & \cdots & a_i^k
\end{bmatrix}
\end{bmatrix}
\]

Now consider an \( n \)-tuple \( x = (x_1, \ldots, x_n) \in A^n \) formed in the following way:

\[
x = (a, \ldots, b, a_1^{i_1}, \ldots, a_1^{i_{k_1}}, \ldots, a_{i_k}^{i_k}, \ldots, a_{i_k}^{i_{k_k}}),
\]

where \( 1 \leq i_1, i_2, \ldots, i_k \leq t \). In other words, for each \( i \) we select one of the rows in the array beneath \( S_i \). Since each \( \pi_i, \delta_i \) is a permutation on \( A \), then \( |P| = t^k \). It follows from the definition that \( P \) is a \( k \)-parameter set in \( A^n \) iff \( P \) can be generated by some expression of the form

\[
\begin{bmatrix}
S_0 & S_1 & S_k \\
\begin{bmatrix}
a \cdots b & \pi_1 & \cdots & \delta_1 & \cdots & \pi_k & \cdots & \delta_k
\end{bmatrix}
\end{bmatrix}
\]

(1)

**Definition 2.** If \( P_i \) is an \( l \)-parameter set in \( A^n \), we say that \( P_k \) is a \( k \)-parameter subset of \( P_i \) if \( P_k \) is a \( k \)-parameter set in \( A^n \) and \( P_k \) is a subset of \( P_i \) (with the same \( A, B, H, n \)).

We point out here that a set of \( t^k \) points of \( A^n \) may possibly have many representations of the form (1). It is a \( k \)-parameter set, however, iff there is at least one such representation.

For example, for any choice of \( \sigma_1, \sigma_2, \ldots, \sigma_n \in H \) the set denoted by

\[
\begin{bmatrix}
S_1 & S_2 & S_n \\
\begin{bmatrix}
\sigma_1 & \sigma_2 & \cdots & \sigma_n
\end{bmatrix}
\end{bmatrix}
\]

is just \( A^n \), which is an \( n \)-parameter subset of itself.

Consider a \( k \)-parameter set \( P_k \) in \( A^n \), say,

\[
P_k = \begin{bmatrix}
S_0 & S_1 & S_k \\
\begin{bmatrix}
a \cdots & b & \pi_1 & \cdots & \delta_1 & \cdots & \pi_k & \cdots & \delta_k
\end{bmatrix}
\end{bmatrix}
\]
For a fixed $i$, $1 \leq i \leq k$, choose an element $\beta \in H$, and form the $k$-parameter set

$$P'_k = [\bar{a} \cdots \bar{b} \pi_1 \cdots \delta_1 \cdots \beta \pi_i \cdots \beta \delta_i \cdots \pi_k \cdots \delta_k].$$

In other words, all the $f(j)$ for $j \in S_i$ have been replaced by $\beta f(j)$.

**Proposition 1.** $P_k = P'_k$.

**Proof.** It is sufficient to show $P_k \equiv P'_k$ since $|P_k| = |P'_k| = t^k$. Let $x \in P'_k$. Then

$$x = (a, \ldots, b, a_{j_1}^{\pi_1}, \ldots, a_{j_1}^{\delta_1}, \ldots, a_{j_2}^{\pi_2}, \ldots, a_{j_2}^{\delta_2}, \ldots, a_{j_t}^{\pi_t}, \ldots, a_{j_t}^{\delta_t})$$

for some $1 \leq j_1, j_2, \ldots, j_t \leq t$. But $a_{j_i}^{\beta} = a_m$ for some $m$ since $\beta \in H$. Also

$$a_{j_i}^{\pi_i} = (a_{j_i}^{\pi_i})^{\pi_i} = a_{m}^{\pi_i},$$

$$\vdots$$

$$a_{j_i}^{\delta_i} = (a_{j_i}^{\delta_i})^{\delta_i} = a_{m}^{\delta_i}.$$

Hence,

$$x = (a, \ldots, b, a_{j_1}^{\pi_1}, \ldots, a_{j_1}^{\delta_1}, \ldots, a_{j_2}^{\pi_2}, \ldots, a_{j_2}^{\delta_2}, \ldots, a_{j_t}^{\pi_t}, \ldots, a_{j_t}^{\delta_t}) \in P_k.$$

Therefore, $P'_k \equiv P_k$ and the proof is complete.

If we premultiply by $\pi_1^{-1}$ each $f(j)$ for $j \in S_k$, then $P_k$ assumes the form

$$P_k = [\bar{a} \cdots \bar{b} \pi_1 \cdots \delta_1 \cdots e \cdots \pi_1^{-1} \delta_1 \cdots e \cdots \pi_k^{-1} \delta_k],$$

where $e$ denotes the identity element of $H$. We may perform this premultiplication for each $i$, $1 \leq i \leq k$.

Further, assume that for each $i > 0$, the minimal element $j$ of $S_i$ has $f(j) = e$ and this entry is written as the leftmost entry under $S_i$. This brings $P_k$ into the form

$$P_k = [\bar{a} \cdots \bar{b} \pi_1^{-1} \delta_1 \cdots e \cdots \pi_1^{-1} \delta_1 \cdots e \cdots \pi_k^{-1} \delta_k].$$

This is a canonical form for $k$-parameter sets, in the sense of the following proposition.

**Proposition 2.** Let

$$P_k = P(A, \bar{B}, H, \Pi, f, n, k) = [\bar{a} \cdots \bar{b} \pi_1 \cdots \pi_1^{-1} \delta_1 \cdots \pi_k \cdots \delta_k],$$

$$P'_k = P(A, \bar{B}, H, \Pi', f', n, k) = [\bar{a}' \cdots \bar{b}' \pi_1 \cdots \pi_1^{-1} \delta_1 \cdots \pi_k \cdots \delta_k],$$

where $\gamma_i = \pi_i^{-1} \delta_i$ and $\gamma_i' = \pi_i \delta_i$. Then $P_k \equiv P'_k$. 

**Proof.** Let $x \in P_k$ and $x' \in P'_k$. Then

$$x = (a, \ldots, b, a_{j_1}^{\pi_1}, \ldots, a_{j_1}^{\delta_1}, \ldots, a_{j_2}^{\pi_2}, \ldots, a_{j_2}^{\delta_2}, \ldots, a_{j_t}^{\pi_t}, \ldots, a_{j_t}^{\delta_t}) \in P_k,$$

$$x' = (a', \ldots, b', a'_{j_1}^{\pi_1}, \ldots, a'_{j_1}^{\delta_1}, \ldots, a'_{j_2}^{\pi_2}, \ldots, a'_{j_2}^{\delta_2}, \ldots, a'_{j_t}^{\pi_t}, \ldots, a'_{j_t}^{\delta_t}) \in P'_k.$$
where these representations are in the form just described, and suppose \( P_k = P'_k \). Then \( \Gamma = \Pi' \), and \( f = f' \).

**Proof.** For all \( x = (x_1, \ldots, x_n) \in P_k \), if \( j \in S_0 \) then \( x_j \) is constant, say \( c_j \). Of course, the same is true for all \( x' = (x'_1, \ldots, x'_n) \in P'_k \), i.e., \( x'_j = c_j \). Thus, \( S_0 = S'_0 \) and \( f(j) = f'(j) \) for all \( j \in S_0 = S'_0 \).

Now, suppose \( j \in S_i \cap S'_i \) and let \( j' \notin S_i \cup S_0 \). For \( x = (x_1, \ldots, x_j, \ldots, x_j', \ldots, x_n) \in P_k \), as \( x \) ranges over \( P_k \), the pair \( (x_j, x'_j) \) ranges over all \( t^2 \) pairs \( (a_r, a_s) \), \( a_r, a_s \in A \). Therefore \( j \) and \( j' \) must be in different blocks of the partition \( \Pi' \). Thus, if \( j \) and \( j' \) are in different blocks of \( \Pi \), then they must be in different blocks of \( \Pi' \). By symmetry, this implies \( \Pi = \Pi' \). By suitable relabelling, we get \( S_i = S'_i \), \( 0 \leq i \leq k \).

For some fixed \( i > 0 \) consider \( S_i = S'_i = \{ j_1 < j_2 < \cdots < j_i \} \). By assumption, \( f(j_1) = f'(j_1) = e \). If \( j, j' \in S_i \), then for any \( x = (x_1, \ldots, x_n) \in P_k \), the value of \( x_i \) determines the value of \( x_{j'} \). For if \( x_j = a \), then for exactly one \( q \), \( a^{(q)} = a = a^{(j)} \).

\[
(a^{(q)}f^{(q)})^{-1} = a_q = a^{(r)}^{-1}
\]

and

\[
x_{j'} = a^{(q)} = (a^{(q)}f^{(q)})^{-1} = a^{(q)}^{-1} f^{(q)}.
\]

Since \( S_i = S'_i \), if \( j = j_1 \), then by (2)

\[
a^{(q)} = x_{j'} = a^{(q)(1)}^{-1} f^{(q)} = a^{(q)} f^{(q)} = a^{(q)}.
\]

But as \( x \) ranges over all of \( P_k \), \( x_i (\equiv a) \) ranges over all of \( A \). (3) implies

\[
a^{(q)} = a^{(q)} \quad \text{for all} \quad a \in A.
\]

By the definition of a permutation group (in which any two elements with the same action are identified) we deduce \( f'(j') = f(j') \). Finally, since \( j' \) was an arbitrary element of \( S_i \), and \( i > 0 \) was arbitrary, then \( f = f' \). This establishes the uniqueness of representation in canonical form up to labelling the blocks \( S_i \) of \( \Pi, i > 0 \), and completes the proof of Proposition 2.

3. **k-parameter subsets of an \( l \)-parameter set.** We describe here the structure of the \( k \)-parameter subsets of an \( l \)-parameter set. Let

\[
P_l = [a \cdots b \ e \cdots y_1 \cdots e \cdots y_1] = P(A, B, H, \Pi, f, n, l)
\]

be an \( l \)-parameter set in \( A^n \) and let

\[
P_k = [a' \cdots b' \ e \cdots y'_1 \cdots e \cdots y'_1] = P(A, B, H, \Pi', f', n, k)
\]
be a $k$-parameter subset of $P_i$. (In general, when we write $P_k \subseteq P_i$, we mean that we are using the same $A, B, H$ and $n$.)

If $x = (x_1, \ldots, x_n) \in P_i$ and $j \in S_0$, then $x_j = b$ for some $b \in B$ (fixed for all $x \in P_i$). Thus $x'_j = b$ for all $x' = (x'_1, \ldots, x'_n) \in P_k \subseteq P_i$. Hence, $j \in S'_0$ and $S_0 \subseteq S'_0$.

Next, suppose $x' = (x'_1, \ldots, x'_n) \in P_k$ and $j' \in S'_0$, $j' \notin S_0$. Then $j' \in S_i$ for some $i > 0$. Hence, for some $b \in B$, $x'_j = b$ for all $x' \in P_k$. As stated in the proof of Proposition 2, this determines all the other values $x'_m, m \in S_i$. Thus, if $x'_j$ is constant, then so is $x'_m$, and $S_i \subseteq S'_0$. We can write

$$P_i = [\cdots \cdots e \cdots \gamma_i \cdots],$$

and for some $j$

$$P_k = [\cdots \cdots a^j_1 \cdots a^j_t \cdots \cdots \cdots \cdots \cdots \cdots].$$

Note. Whenever nested boldface lines are used, it indicates that the subsets corresponding to the lower boldface lines are contained in the subsets corresponding to the boldface lines directly above, e.g., in the expression above, $S_i \subseteq S'_0$. In general, the uppermost level of boldface lines correspond to the blocks of the partition for the $k$-parameter subset.

**Proposition 3.** Suppose $j_1 \in S_{i_1} \cap S'_{i_2}$ and $j_2 \in S_{i_2}$. Then $j_2 \in S'_{i_2}$.

**Proof.** Since $j_1$ and $j_2$ are in the same block of $\Pi$, then for any

$$x = (x_1, \ldots, x_{j_1}, \ldots, x_{j_2}, \ldots, x_n) \in P_i,$$

the value of $x_{j_2}$ determines the value of $x_{j_2}$. But $P_k \subseteq P_i$, so this is true for all $x \in P_k$. Hence, $j_1$ and $j_2$ must be in the same block of $\Pi'$, i.e., $j_2 \in S_{i_2}$ as claimed.

We have shown that

$$S_{q_1} \cap S'_{q_2} \neq \emptyset \Rightarrow S_{q_1} \subseteq S'_{q_2}.$$

Thus, $\Pi$ is a refinement of $\Pi'$.

Now, consider $S_q, S_r$ for which $S_q, S_r \subseteq S'_i, q \neq r$. A typical point of $P_k$ is

$$x' = (\ldots \cdots, x_{j_2}, \ldots \cdots, x_{j_3}, \ldots \cdots),$$

where $j_1 \in S_q, j_2, j_3 \in S_r$. For $x'$ in $P_k$, the value of $x_{j_1}$ determines the value of $x_{j_2}$.
Of course, for any \( x \in P_i \), the value of \( x_{i_2} \) determines the value of \( x_{i_3} \). More precisely we have

\[
P_i = \begin{bmatrix} \cdots & e \cdots \gamma_q & \cdots & e \cdots \gamma_r & \cdots \end{bmatrix}
\]

\[
S_q \quad \quad \quad \quad \quad \quad \quad \quad S_r
\]

\[
= \begin{bmatrix} \cdots & a_{1}^q \cdots a_{t_1}^q & \cdots & a_{1}^r \cdots a_{t_1}^r & \cdots \\
 & a_{1}^q \cdots a_{t_2}^q & a_{1}^r \cdots a_{t_2}^r \\
 & \vdots & \vdots & \vdots & \vdots \\
 & a_{1}^q \cdots a_{t_t}^q & a_{1}^r \cdots a_{t_t}^r \\
\end{bmatrix}
\]

and, as \( x \) ranges over \( P_i \),

\[
S_q \quad \quad \quad \quad \quad \quad \quad \quad S_r
\]

\[
x = (\ldots, a_{u_1}^q, \ldots, a_{t_1}^q, \ldots, a_{v_1}^r, \ldots, a_{t_2}^r, \ldots),
\]

all \( t^2 \) possible choices of \( u \) and \( v \), will occur. On the other hand, in \( P_k \), since any value under \( S_q \) determines the values under \( S_r \), we must have

\[
P_k = \begin{bmatrix} \cdots & \pi_{1}^q \cdots \pi_{t_1}^q & \cdots & \pi_{1}^r \cdots \pi_{t_1}^r & \cdots \\
 & \pi_{1}^q \cdots \pi_{t_2}^q & \pi_{1}^r \cdots \pi_{t_2}^r \\
 & \vdots & \vdots & \vdots & \vdots \\
 & \pi_{1}^q \cdots \pi_{t_t}^q & \pi_{1}^r \cdots \pi_{t_t}^r \\
\end{bmatrix}
\]

\[
S_q \quad \quad \quad \quad \quad \quad \quad \quad S_r
\]

\[
= \begin{bmatrix} \cdots & \cdot \cdot \cdot \pi_{t_1}^{-1} \delta_q & \cdots & \pi_{t_1}^{-1} \pi_{t_2}^{-1} \delta_r & \cdots \\
 & \pi_{t_1}^{-1} \pi_{t_2}^{-1} \delta_q & \pi_{t_1}^{-1} \pi_{t_2}^{-1} \delta_r \\
 & \vdots & \vdots & \vdots & \vdots \\
 & \pi_{t_1}^{-1} \pi_{t_t}^{-1} \delta_q & \pi_{t_1}^{-1} \pi_{t_t}^{-1} \delta_r \\
\end{bmatrix},
\]

where we have premultiplied the entries under \( S'_l \) by \( \pi_{t_1}^{-1} \). Since \( P_k \subseteq P_i \) we must have \( \pi_{t_1}^{-1} \delta_q = \gamma_q \) and \( \pi_{t_1}^{-1} \delta_r = \gamma_r \). Hence, we can write \( P_k \) as

\[
P_k = \begin{bmatrix} \cdots & e \cdots \gamma_q & \cdots & (\pi_{t_1}^{-1} \pi_{t_2}^{-1} \pi_{t_t}^{-1} \pi_{t_1} \gamma_{t_1} \gamma_{t_2} \gamma_{t_t}) & \cdots \\
\end{bmatrix}
\]
Thus, in forming $P_k$ from $P_i$ we are permitted to premultiply the entries $f(j), j \in S_n$, by some arbitrary element of $H$ as we form $\Pi'$ from $\Pi$. Conversely, it is clear that this process of premultiplication and joining blocks of $\Pi$ to form those of $\Pi'$ always yields a $k$-parameter subset of $P_i$. We summarize this below.

Let $P=P(A, B, H, \Pi, f, n, l)$ be an $l$-parameter set in $A^n$. The general $k$-parameter subset $P_k \subseteq P_i$ is formed as follows: Let $\Pi'$ be a partition of which $\Pi$ is a refinement, say, $\Pi' = \{S'_0, S'_1, \ldots, S'_k\}$ with $S_0 \subseteq S'_0$ and $S'_i \not= \emptyset$, $i > 0$. For each $S_i \subseteq S'_0$, $i > 0$, choose $\tau_i \in B$; for each $S_i \not\subseteq S'_0$, choose $\tau_i \in H$. Define $f': I_n \rightarrow H \cup B$ by

$$f'(j) = \tau_i f(j), \quad j \in S_i, i > 0,$$

$$f'(j) = f(j), \quad j \in S'_0.$$

Then $P_k = P(A, B, H, \Pi', f', n, k)$ is a $k$-parameter set in $A^n$, $P_k \subseteq P_i$, and all $k$-parameter subsets of $P_i$ can be obtained this way (though not necessarily in canonical form).

4. Construction of *-sets. We now give a new construction which will be essential in the remainder of the paper. What we do is replace $A$ by the set of images \{\(l^e : s \in A \cup H\)\} and establish corresponding notation while retaining that of the preceding section. Define

$$L_A = \{l^a : a \in A\} = \{(a, \ldots, a) : a \in A\} \subseteq A^i,$$

$$L_B = \{l^b : b \in B\},$$

$$L_H = \{l^\sigma : \sigma \in H\},$$

$$L = L_A \cup L_H = \{l_1, \ldots, l_n\} \subseteq A.$$

For $x=(x_1, \ldots, x_n) \in L^n$, $\sigma \in H$, we define an action of $H$: $L^n \rightarrow L^n$ by

$$x^\sigma = (x_1^\sigma, \ldots, x_n^\sigma).$$

Similarly, define $\bar{B}: L^n \rightarrow L^n$ by

$$x^b = (x_1^b, \ldots, x_n^b).$$

For all $l, m \in L$, define the map $l: L \rightarrow L$ by

$$m^l = l.$$

This induces a map $l: L^n \rightarrow L^n$ by

$$x^l = (x_1^l, \ldots, x_n^l) = (l, \ldots, l) \in L^n.$$

Finally we make the following definitions:

$$l^e = (l^1, \ldots, l^n) \in L^n,$$

$$C = L_H \cup L_B, \quad \bar{C} = \{\bar{c} : c \in L_H \cup L_B\},$$

$$L_{H}^* = \{l^\sigma : \sigma \in H\}, \quad L_{B}^* = \{l^\bar{c} : \bar{c} \in \bar{C}\}.$$
As before, we have the notation of $k$-parameter sets in $L^n$. We note that the representation of $H$ as a permutation group on $L$ is faithful. For $L^n$ we modify the notation slightly by writing a $k$-parameter set $P^*_k = P(L, \overline{C}, H, \Pi^*, g, n, k)$ as

\[
\begin{array}{ccc}
S^*_0 & S^*_1 & S^*_k \\
T^*_0 & V^*_0 & \pi_1 \cdots \delta_1 & \cdots & \pi_k \cdots \delta_k,
\end{array}
\]

where $l_0^0, \ldots, l_0^n \in L_B$ and $l_0^0, \ldots, l_0^n \in L_H$ (i.e., $\pi_0, \ldots, \delta_0 \in H$). Slightly expanded, this is

\[
\begin{array}{c|c|c|c|c|c}
 & S^*_0 & S^*_1 & \cdots & S^*_k \\
T^*_0 & V^*_0 & \pi_1 & \cdots & \delta_1 & \cdots & \pi_k & \cdots & \delta_k \\
\hline
(l_0^0, \ldots, l_0^n, l_0^0, \ldots, l_0^n) & (l_0^0)^{\pi_1} \cdots (l_0^n)^{\delta_1} & \cdots & (l_0^0)^{\pi_k} \cdots (l_0^n)^{\delta_k} \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \vdots \\
(l_0^0, \ldots, l_0^n, l_0^0, \ldots, l_0^n) & (l_0^0)^{x_1} \cdots (l_0^n)^{y_1} & \cdots & (l_0^0)^{x_k} \cdots (l_0^n)^{y_k} \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \vdots \\
(l_0^0, \ldots, l_0^n, l_0^0, \ldots, l_0^n) & (l_0^0)^{x_1} \cdots (l_0^n)^{y_1} & \cdots & (l_0^0)^{x_k} \cdots (l_0^n)^{y_k} \\
\end{array}
\]

\( (u \text{ rows}) \)

5. The map $M$. We define a map $M : L^n \to 2^{A^n}$ as follows: For $x = (x_1, \ldots, x_n) \in L^n$, $x = (x_{11}, \ldots, x_{1l}) \in L \subseteq A^l$, $1 \leq i \leq n$, let

\[
M(x) = \left\{ \begin{array}{l}
(x_{11}, x_{21}, \ldots, x_{n1})_1, \\
(x_{12}, x_{22}, \ldots, x_{n2})_2, \\
\vdots \\
(x_{1l}, x_{2l}, \ldots, x_{nl})_l
\end{array} \right\} \subseteq A^n.
\]

For $S \subseteq L^n$ we define $M(S)$ to be $\bigcup_{s \in S} M(s)$.

Suppose

\[
\begin{array}{ccc}
S^*_0 & S^*_1 & S^*_k \\
T^*_0 & V^*_0 & \pi_1 \cdots \delta_1 & \cdots & \pi_k \cdots \delta_k
\end{array}
\]

is a $k$-parameter set in $L^n$. Let us examine $M(P^*_k)$.

**Proposition 4.** If $V^*_0 \neq \emptyset$, then $M(P^*_k)$ is the $(k+1)$-parameter set $P^*_{k+1}$ in $A^n$ given by

\[
\begin{array}{ccc}
S_0 = T^*_0 & S_1 = V^*_0 & S_2 = S^*_1 \\
S_{k+1} = S^*_k
\end{array}
\]

\[
P^*_{k+1} = [l_0^0, \ldots, l_0^n, l_0^0, \ldots, l_0^n, \pi_0, \ldots, \delta_0, \pi_1, \ldots, \delta_1, \ldots, \pi_k, \ldots, \delta_k].
\]
Proof. We first show $P_{k+1} \subseteq M(P^*_k)$.
Let $x \in P_{k+1}$. Then
\[
\begin{array}{cccc}
T^*_0 & V^*_0 & S^*_1 & S^*_k \\
x = (b \cdots d a^*_0 \cdots a^*_k a^*_{11} \cdots a^*_{k1} \cdots a^*_{k2} \cdots a^*_{k3}),
\end{array}
\]
where we shall delete the commas between successive entries for notational convenience. In $P^*_k$ we choose
\[
\begin{array}{ccc}
S^*_0 & S^*_1 & S^*_k \\
T^*_0 & V^*_0 &
\end{array}
\]
\[
x^* = (l^*_0 \cdots l^*_d l^*_0 \cdots l^*_d (l^*_0)^*_1 \cdots (l^*_0)^*_k \cdots (l^*_d)^*_1 \cdots (l^*_d)^*_k).
\]
Thus
\[
M(x^*) = \begin{cases} 
T^*_0 & V^*_0 & S^*_1 & S^*_k \\
(b \cdots d a^*_0 \cdots a^*_k a^*_{11} \cdots a^*_{k1} \cdots a^*_{k2} \cdots a^*_{k3}), \\
(b \cdots d a^*_0 \cdots a^*_k a^*_{11} \cdots a^*_{k1} \cdots a^*_{k2} \cdots a^*_{k3}), \\
\vdots & \vdots & \vdots & \vdots \\
(b \cdots d a^*_0 \cdots a^*_k a^*_{11} \cdots a^*_{k1} \cdots a^*_{k2} \cdots a^*_{k3}), \\
(b \cdots d a^*_0 \cdots a^*_k a^*_{11} \cdots a^*_{k1} \cdots a^*_{k2} \cdots a^*_{k3})
\end{cases}.
\]
Therefore $x \in M(x^*)$ and $P_{k+1} \subseteq M(P^*_k)$.
We next show $P_{k+1} \supseteq M(P^*_k)$.
Let $y^* \in P^*_k$.
\[
\begin{array}{ccc}
S^*_0 & S^*_p & S^*_q \\
T^*_0 & V^*_0 &
\end{array}
\]
\[
y^* = (l^*_0 \cdots l^*_d l^*_0 \cdots l^*_d (l^*_0)^*_p \cdots (l^*_0)^*_q \cdots (l^*_d)^*_p \cdots (l^*_d)^*_q).
\]
The entries under $S^*_p$ and $S^*_q$ represent the two possible forms which might occur. Thus,
\[
M(y^*) = \begin{cases} 
T^*_0 & V^*_0 & S^*_p & S^*_q \\
(b \cdots d a^*_0 \cdots a^*_k a^*_{11} \cdots a^*_{k1} \cdots a^*_{k2} \cdots a^*_{k3}), \\
\vdots & \vdots & \vdots & \vdots \\
(b \cdots d a^*_0 \cdots a^*_k a^*_{11} \cdots a^*_{k1} \cdots a^*_{k2} \cdots a^*_{k3}), \\
\vdots & \vdots & \vdots & \vdots \\
(b \cdots d a^*_0 \cdots a^*_k a^*_{11} \cdots a^*_{k1} \cdots a^*_{k2} \cdots a^*_{k3})
\end{cases}.
\]
A typical point of $M(y^*)$ is given by

$$
S_0 = T_0^* \quad S_1 = V_0^* \quad S_{p+1} = S_p^* \quad S_{q+1} = S_q^*
$$

$$
y = (b \cdots d \quad a_0^{\pi_0} \cdots a_0^{\delta_0} \quad \cdots \quad a_p^{\pi_p} \cdots a_p^{\delta_p} \quad \cdots \quad a_q^{\pi_q} \cdots a_q^{\delta_q} \cdots).
$$

We see that $y \in P_{k+1}$ since the entries under each $S_i$ are of the appropriate type. Therefore $M(P_k^*) \subseteq P_{k+1}$. This, together with the opposite inclusion establishes Proposition 4.

6. The commutative diagram. We come to the basic property of $M$. Suppose

$$
\begin{array}{ccc}
S_0^* & S_1^* & S_{l^*}^* \\
T_0^* & V_0^* & \\
\kappa_i & [\kappa_i] & \pi_0 \cdots \delta_0 \\
\end{array}
$$

is an $l$-parameter set in $L^n$ with $V_0^* \neq \emptyset$. Let

$$
P_{i+1} = M(P_i^*) = [b \cdots d \quad \pi_0 \cdots \delta_0 \quad \pi_1 \cdots \delta_1 \quad \cdots \quad \pi_1 \cdots \delta_1]
$$

denote the induced $(l+1)$-parameter set in $A^n$. Further, suppose $P_{k+1}$ is a $(k+1)$-parameter subset of $P_{i+1}$ in which $T_0^*$ and $V_0^*$ are not in the same block of the partition for $P_{k+1}$. We might write $P_{k+1}$, for example, as

$$
\begin{array}{ccc}
S_0' & S_1' & S_{k+1}' \\
T_0^* & S_1^* & S_2^* & S_3^* & S_{k+1}^* \\
\pi_0 \cdots \delta_0 & \sigma_3 \pi_3 \cdots \sigma_3 \delta_3 & \cdots & \sigma_{14} \pi_{14} \cdots \sigma_{14} \delta_{14} & \cdots & \sigma_{14} \pi_{14} \cdots \sigma_{14} \delta_{14} \\
S_2^* & S_3^* & & & & \\
S_3^* & S_4^* & S_{k+1}^* \\
\sigma_9 \pi_9 \cdots \sigma_9 \delta_9 & \cdots & \sigma_{14} \pi_{14} \cdots \sigma_{14} \delta_{14} & \cdots & \sigma_{14} \pi_{14} \cdots \sigma_{14} \delta_{14} & \cdots & \sigma_{14} \pi_{14} \cdots \sigma_{14} \delta_{14} \\
\end{array}
$$

where we have adjusted the group elements in $S_1'$ by choosing the premultiplying factor of $V_0^*$ to be the identity element $e$.

**Proposition 5.** There exists a $k$-parameter subset $P_k^*$ of $P_i^*$ such that the following diagram is commutative:

$$
\begin{array}{ccc}
P_k^* \subseteq P_i^* \\
M \downarrow \quad M \\
\sigma_{k+1} \subseteq P_{i+1}.
\end{array}
$$
**Proof.** Our candidate for $P_k^*$ is, of course,

\[
S_0^* \quad T_0^* = S_0^* \quad V_0^* = S_1^* \\
S_1^* \quad T_1^* \quad S_2^* \quad V_1^* \quad S_3^* \quad S_{11}^* \\
P_k^* = \{ \overline{I}_0 \ldots \overline{I}_0 \overline{I}_0^{\alpha_1} \ldots \overline{I}_0^{\alpha_1} \ldots \overline{I}_0^{\alpha_1} \ldots \overline{I}_0^{\alpha_1} \overline{I}_0^{\alpha_2} \ldots \overline{I}_0^{\alpha_2} \ldots \overline{I}_0^{\alpha_2} \ldots \overline{I}_0^{\alpha_2} \overline{I}_0^{\alpha_3} \ldots \overline{I}_0^{\alpha_3} \ldots \overline{I}_0^{\alpha_3} \ldots \overline{I}_0^{\alpha_3} \overline{I}_0^{\alpha_4} \ldots \overline{I}_0^{\alpha_4} \ldots \overline{I}_0^{\alpha_4} \ldots \overline{I}_0^{\alpha_4} \overline{I}_0^{\alpha_5} \ldots \overline{I}_0^{\alpha_5} \ldots \overline{I}_0^{\alpha_5} \ldots \overline{I}_0^{\alpha_5} \}
\]

We check:

(i) $P_k^*$ is a $k$-parameter set in $L^n$ since $S_0^*, \ldots, S_{k+1}^*$ are all nonempty,

(ii) $M(P_k^*) = P_{k+1}$ is immediate by the construction of $P_k^*$,

(iii) $P_k^* \subseteq P_k^*$. This follows by inspection.

This completes the proof.

7. **The main result.** Before proceeding with the main result of the paper we make a remark on terminology.

**Definition 3.** By an $r$-coloring of a set $X$ we just mean a partition of $X$ into $r$ disjoint (possibly empty) classes.

Of course, the "$r$ colors" correspond to the $r$ classes into which $X$ is partitioned. In general, we shall use this "chromatic" terminology in preference to that of partitions and classes.

**Theorem.** Given $A, B, H$ and integers $k, r, t_1, \ldots, t_r$, there exists an $N = N(A, B, H, k, r, t_1, \ldots, t_r)$ such that if $n \geq N$ and $P_n = P(A, B, H, \Pi, f, w, n)$ is any fixed $n$-parameter set in $A^w$, then for any $r$-coloring of the $k$-parameter subsets of $P_n$ there exists an $i, 1 \leq i \leq r$, such that there is some $t_i$-parameter subset of $P_n$ with all its $k$-parameter subsets having color $i$.

**Proof.** The proof will proceed basically by double induction on $k$ and $t_1 + \cdots + t_r$. We defer the proof for $k = 0$ until later. For a fixed integer $k \geq 0$ assume the theorem has been established for this $k$ and all values of $r, t_1, \ldots, t_r$. We prove the theorem for $k + 1$. Of course, the theorem is immediate for $r = 1$, and it is true vacuously for $t_1 + \cdots + t_r \leq (k+1)r - 1$ (since in this case, for some $i, t_i < k + 1$). Henceforth we assume that $r \geq 2$, and $t_i \geq k + 1$, and furthermore that for some $p$ the theorem holds when $t_1 + \cdots + t_r = p$. We must now prove the theorem with $t_1 + \cdots + t_r = p + 1$.

**Definition 4.** Let $P_m = P(X, Y, G, \Pi, f, w, m)$ be an $m$-parameter set in $X^w$, where $\Pi$ is the partition $\{S_0, S_1, \ldots, S_m\}$. Then for $k \leq m$ and $1 \leq i \leq m$, an $S_i$-crossing $k$-parameter subset of $P_m$ is a $k$-parameter subset $P_k = P(X, Y, G, \Pi', f', w, k)$ where the partition $\Pi' = \{S_0, S_1', \ldots, S_k\}$, and $S_i \not\subseteq S_0$. 
We now prove two lemmas. The first says that for large enough \( m \), we can extract from an \((m+1)\)-parameter set an \((l+1)\)-parameter set which is decomposed into disjoint “parallel hyperplanes,” and such that the \((k+1)\)-parameter subsets which “cut across” the hyperplanes (i.e., do not lie within any of them) all have the same color. The second lemma is the iteration of the first, and says that we can extract such a subset with many such decompositions (in different “directions”) with monochromatic crossing subsets.

Let \( L, C \) and the map \( M \) be as before.

**Lemma 1.** Let \( P_{m+1} \) denote \( P(A, \overline{B}, H, \Pi, f, w, m+1) \) be an \((m+1)\)-parameter set in \( A^w \) with partition \( \Pi = \{ S_0, S_1, \ldots, S_{m+1} \} \). Let \( l \geq 0 \) be an integer. If \( m \geq N(L, C, H, k, r, l, \ldots, l) \) \( (l \text{ taken } r \text{ times}), \) which is meaningful by the induction hypothesis, then for any fixed \( i, 1 \leq i \leq m+1 \), and for any \( r \)-coloring of the \((k+1)\)-parameter subsets of \( P_{m+1} \), there is a \( S_i \)-crossing \((l+1)\)-parameter subset \( P_{i+1} \) of \( P_{m+1} \) such that for some \( j, 1 \leq j \leq r \), all the \( S_j \)-crossing \((k+1)\)-parameter subsets of \( P_{i+1} \) have color \( j \).

**Proof of Lemma 1.** Let \( P_m^* \) denote the \( m \)-parameter set in \( L^w \) which has partition \( \Pi^* = \{ S_0^*, S_1^*, \ldots, S_m^* \} \) and such that \( M(P_m^*) = P_{m+1} \) (where \( \{ S_1^*, \ldots, S_m^* \} \) is some relabelling of \( \{ S_1, \ldots, S_{l-1}, S_{l+1}, \ldots, S_{m+1} \} \)). We remark that if \( P_k^* \) is a \( k \)-parameter subset of \( P_m^* \), then \( M(P_k^*) \) is an \( S_i \)-crossing \((k+1)\)-parameter subset of \( P_{m+1} \) by the definition of \( P_m^* \) and \( M \).

The given \( r \)-coloring of the \((k+1)\)-parameter subsets of \( P_{m+1} \) induces an \( r \)-coloring of the \( k \)-parameter subsets of \( P_m^* \) in the following way: \( P_k^* \) is given the same color as \( P_{k+1} = M(P_k^*) \). By the remark above this is a well-defined \( r \)-coloring of the \( k \)-parameter subsets of \( P_m^* \). By the choice of \( m \), there exists an \( l \)-parameter subset \( P_i^* \subseteq P_m^* \) such that all the \( k \)-parameter subsets of \( P_i^* \) have one color, say color \( j \). But \( P_{i+1} = M(P_i^*) \) is an \( S_i \)-crossing \((l+1)\)-parameter subset of \( P_{m+1} \). By Proposition 5, every \( S_i \)-crossing \((k+1)\)-parameter subset of \( P_{i+1} \) is the image under \( M \) of a \( k \)-parameter subset of \( P_i^* \). Thus, all these have color \( j \) and the lemma is proved.

At this point we find it convenient to assume that \( B = A \). We proceed to prove the theorem for this case, and then, as a direct corollary (Lemma 3 below), we establish the general result. Thus, let \( A = B \), and let \( C, H, L \) and \( M \) be as before.

Let \( P_m^* = P(L, C, H, \Pi, f, w, m) \) be an \( m \)-parameter set in \( L^w \) with partition \( \Pi^* = \{ T_0^* \cup V_0^* = S_0^*, S_1^*, \ldots, S_m^* \}, V_0^* \neq \emptyset \). Then \( M(P_m^*) \) is an \((m+1)\)-parameter set in \( A^w \). Let \( P_{i+2} \) be a \( V_0^* \)-crossing \((l+2)\)-parameter subset of \( M(P_m^*) \),

\[
P_{i+2} = [\delta_0 \cdot \delta_0 \cdots \delta_0] = \begin{array}{cccc}
S_0 & S_1 & S_2 & S_{i+2} \\
V_0^* & & & \\
\pi_0 \cdots \sigma_i \cdots \sigma_j \cdots \delta_i & \pi_0 \cdots \sigma_i \cdots \delta_i & \pi_0 \cdots \sigma_i \cdots \delta_i & \pi_0 \cdots \sigma_i \cdots \delta_i
\end{array}
\]

Then \( P_{i+2} \) is the disjoint union of \( t \) \((l+1)\)-parameter subsets \( P_{i+1} \), \( 1 \leq i \leq t \), none of
which are $V_0^\ast$-crossing subsets, defined by

\[
\begin{array}{cccc}
S_0' & S_1' & S_1 = S_2 & S_{l+2} = S_{l+2} \\
S_0 & S_1 & V_0^\ast & S_1^* \\
\end{array}
\]

\[P_{l+1} = [b \ldots d \overline{a_1^{\pi_0}} \ldots \overline{a_l^{\pi_0}} \ldots \overline{a_1^{\pi_1 \delta_1}} \ldots \overline{a_l^{\pi_1 \delta_1}} \ldots \pi \ldots \ldots \delta].\]

**Definition 5.** The $P_{l+1}$ are called $V_0^\ast$-translates of each other in $P_{l+2}$ (or just translates when no confusion arises).

**Remark 1.** Let $P_{l+2}$ be a $V_0^\ast$-crossing $(l+2)$-parameter subset of $M(P_n^\ast)$ with $V_0^\ast$-translates $P_{l+1}$ as above, and let $P_{k+2}$ be a $V_0^\ast$-crossing $(k+2)$-parameter subset of $P_{l+2}$. Then

\[
\begin{array}{cccc}
S_0' & S_1' & S_2' & S_{k+2}' \\
S_0 & S_1 & V_0^\ast & S_1^* \\
S_0 & S_1 & V_0^\ast & S_1^* \\
\end{array}
\]

\[P_{k+2} = [b \ldots d \ldots \pi_0 \ldots \delta_0 \ldots \sigma_j \pi_j \ldots \sigma_j \delta_j \ldots \tau \ldots \gamma \ldots \pi' \ldots \ldots \delta'].\]

$P_{k+2}$ is the disjoint union of the $t$ $V_0^\ast$-translates $P_{k+1}$, where

\[
\begin{array}{cccc}
S_0' & S_1' & S_2' & S_{k+1}' \\
S_0 & S_1 & V_0^\ast & S_1^* \\
\end{array}
\]

\[P_{k+1} = [b \ldots d \ldots \overline{a_1^{\pi_0}} \ldots \overline{a_l^{\pi_0}} \ldots \overline{a_1^{\pi_1 \delta_1}} \ldots \overline{a_l^{\pi_1 \delta_1}} \ldots \overline{a_l'} \ldots \overline{a_l'} \ldots \ldots \delta'].\]

We see that $P_{k+1} \subseteq P_{l+1} \cap P_{k+2}$ because $P_{k+1} \subseteq P_{l+1}$ and $P_{k+2} \subseteq P_{l+2}$. On the other hand, any point in $P_{l+1} \cap P_{k+2}$ must be in $P_{k+1}$ as can be checked by verifying the inclusion properties of $n$-parameter sets. Thus, $P_{k+1} = P_{l+1} \cap P_{k+2}$.

**Remark 2.** If $P_{k+1}$ is any $(k+1)$-parameter subset of $P_{k+1}$, then there is some $V_0^\ast$-crossing $(k+2)$-parameter subset of $P_{l+2}$ with $P_{k+2} = \bigcup_{j=1}^t P_{k+1}^j$, the $P_{k+1}^j$ being $V_0^\ast$-translates, such that $P_{k+1} = P_{k+1}^1$. In particular, taking $P_{l+1}$ to be as in Definition 5, $P_{k+1} \subseteq P_{l+1}$ must look like

\[
\begin{array}{ccc}
S_0' & S_1' & S_{k+1}' \\
S_0 & S_1 & V_0^\ast & S_1^* \\
\end{array}
\]

\[P_{k+1} = [b \ldots d \ldots \overline{a_1^{\pi_0}} \ldots \overline{a_l^{\pi_0}} \ldots \overline{a_1^{\pi_1 \delta_1}} \ldots \overline{a_l^{\pi_1 \delta_1}} \ldots \overline{a_l'} \ldots \overline{a_l'} \ldots \ldots \delta'].\]
Then we can take

\[
\begin{array}{cccc}
S_0^w & S_1^w & S_2^w & S_{k+2}^w = S_{k+1}^w \\
S_0 & S_2 & V_0^* & S_1^* \\
P_{k+2} = [b \ldots d \ldots a_1^i \ldots a_2^j \ldots \pi_0 \ldots \delta_0 \ldots \sigma_{f,j} \ldots \sigma_{f,i} \ldots \pi' \ldots \delta']
\end{array}
\]

This choice of \(P_{k+2}\) is well defined. That is, \(S_1^w = S_1\) is the smallest set we can choose from \(S_0^w\) to generate a \((k+2)\)-parameter set which is \(V_0^*-\text{crossing}\) and is contained in \(P_{k+2}\) (since any such \(S_1^w\) must contain \(S_1\)). We shall refer to this particular \(P_{k+2}\) as the \(V_0^*-\text{expansion of } P_{k+1}\) in \(P_{k+2}\).

Remark 3. It should be noted that if \(P_{k+1}\) is any \((k+1)\)-parameter subset of \(P_{k+2}\), then either \(P_{k+1}\) is a \(V_0^*-\text{crossing } (k+1)\)-parameter set or \(P_{k+1} \subseteq P_{i+1}\) for some \(i\). This follows from the way in which the \((k+1)\)-parameter subsets of \(P_{k+2}\) must be formed.

Definition 6. Let \(A = B, H\) be as above. Let \(P_{m+v}\) be an \((m+v)\)-parameter subset of \(A^w\) with partition \(\{S_0, S_1, \ldots, S_v, V_1, \ldots, V_m\}\). For each \(i, 1 \leq i \leq m\), \(P_{m+v}\) is the union of \(t\) disjoint \((m+v-1)\)-parameter subsets \(P_{(m+v-1),t}^i, 1 \leq j \leq t, \) which are \(V_i\)-translates of each other. Let \(P_{k+1}\) be a \((k+1)\)-parameter subset of \(P_{m+v}\), which is \(V_i\)-crossing for at least one \(i\). Let \(l = m - \max \{i : P_{k+1} \subseteq V_i\}\). Then we associate with \(P_{k+1}\) the \((l+1)\)-tuple \((i; j_m, j_{m-1}, \ldots, j_{m-l+1})\), where for \(m-l < i \leq m\) we define \(j_i\) by \(P_{k+1} \subseteq P_{m+v-1,l}^i\). (For \(l=0\) we get merely \((0)\).) We call this the signature of \(P_{k+1}\) in \(P_{m+v}\) with respect to \((V_1, V_2, \ldots, V_m)\). An \(r\)-coloring of the \((k+1)\)-parameter subsets of \(P_{m+v}\) will be called a \((V_1, V_2, \ldots, V_m)\)-coloring if the colors of all \((k+1)\)-parameter subsets with the same signature are the same.

We next present an iterated form of Lemma 1. For arbitrary positive integers \(m\) and \(v\), define the integers \(v_i, 1 \leq i \leq m\), as follows:

\[
v_1 = N(L, C, H, k, r^{m-1}, v, \ldots, v),
\]

\[
v_2 = N(L, C, H, k, r^{m-2}, v_1 + 1, \ldots, v_1 + 1),
\]

\[
\vdots
\]

\[
v_{i+1} = N(L, C, H, k, r^{m-i-1}, v_i + 1, \ldots, v_i + 1),
\]

\[
\vdots
\]

\[
v_m = N(L, C, H, k, r^0, v_{m-1} + 1, \ldots, v_{m-1} + 1).
\]

Lemma 2. Let \(m\) and \(v\) be positive integers, let \(A = B\). Let \(P_x = P(A, B, H, \Pi, f, w, x)\) be an \(x\)-parameter set in \(A^w\) with \(x \geq v_m\). Suppose the \((k+1)\)-parameter subsets of \(P_x\) are \(r\)-colored. Then \(P_x\) contains an \((m+v)\)-parameter subset \(P_{m+v}\), with partition \(\{S_0, S_1, \ldots, S_v, V_1, \ldots, V_m\}\), such that the \(r\)-coloring restricted to \(P_{m+v}\) is a \((V_1, V_2, \ldots, V_m)\)-coloring.

Proof. We remark first that if \(m=1\), this lemma asserts that there is a \(P_{v+1}\) such that all of its \(V_1\)-crossing \(P_{k+1}\) have one color. This is just the conclusion of Lemma 1.

Assume, then, that Lemma 2 is true for \(m-1\). We show that it is true for \(m\). Let
\[ v_{m-1} = v_m, \ldots, v'_1 = v_2, \quad v' = v_1 + 1. \] Then, by induction, there is some \((m-1+v')\)-parameter subset \(P_{v_1 + m} \subseteq P_{x_1}\) with partition \(\{S'_0, S'_1, \ldots, S'_{v_1 + 1}, V'_1, \ldots, V'_{m-1}\}\), such that \(P_{v_1 + m}\) is \((V'_{m-1}, \ldots, V'_1)\)-colored.

Let \((P_{v_1 + m + v_1 - 1}^i)\), \(1 \leq i \leq t\), be \(V'_i\)-translates in \(P_{v_1 + m}\). Let \(P_{v_1 + 1} = \bigcap_{i=1}^{n-1} (P_{v_1 + v_1 - 1, i})'\). This is a \((v_1+1)\)-parameter subset of \(P_{v_1 + m}\) with partition \(\{S'_0 \cup V'_1 \cup \cdots \cup V'_{m-1}, S'_1, \ldots, S'_{v_1 + 1}\}\). Let \(P_{k+1}\) be a \((k+1)\)-parameter subset of \(P_{v_1 + 1}\), and let \(P_{k+m}\) be the \(V'_1\)-expansion of the \(V'_2\)-expansion of \(\ldots\) of the \(V'_{m-1}\)-expansion of \(P_{k+1}\). Then for each choice of \((j_1, \ldots, j_{m-1})\), \(P_{k+m} \cap \bigcap_{i=1}^{n-1} (P_{h + v_1 + 1, i})'\) is a \((k+1)\)-parameter subset. This \((k+1)\)-parameter subset has some color. Thus, for each \(P_{k+1}\) in \(P_{v_1 + 1}\) there is a color associated with each of the \(t^{m-1}\) choices of the \(j_i\)'s. Using this, we can recolor the \((k+1)\)-parameter subsets of \(P_{v_1 + 1}\) by letting two of them have the same new color if and only if for each choice of the \(j_i\)'s the associated (old) color is the same. This is an \(r^{m-1}\)-coloring of the \((k+1)\)-parameter subsets of \(P_{v_1 + 1}\).

By the choice of \(v_1\), and by Lemma 1, there is some \((v+1)\)-parameter subset \(P_{v+1} \subseteq P_{v_1 + 1}\), with partition \(\{S'_0, S'_1, \ldots, S'_v, V'_1\}\), such that all \(V'_1\)-crossing \((k+1)\)-parameter subsets of \(P_{v+1}\) have the same new color. Let \(P_{m+v}\) be the \(V'_i\)-expansion of the \(V'_2\)-expansion of \(\ldots\) of the \(V'_{m-1}\)-expansion of \(P_{v+1}\). By iteration of Remark 2, every \((k+1)\)-parameter subset of \(P_{m+v}\) which is not \(V'_i\)-crossing for any \(i, 1 \leq i \leq m-1\), is in the \(V'_i\)-expansion of \(\ldots\) of the \(V'_{m-1}\)-expansion of some \((k+1)\)-parameter subset of \(P_{v+1}\). By the definition of the new coloring, and the choice of \(P_{m+v}\), any \((k+1)\)-parameter subset of \(P_{m+v}\) which is \(V'_1\)-crossing but not \(V'_i\)-crossing for any \(i, 1 \leq i \leq m-1\), has its (old) color determined only by its corresponding \(j_i\)'s (i.e., its signature with respect to \(V'_1, \ldots, V'_{m-1}\)).

If \(V'_2 = V'_1, \ldots, V'_m = V'_{m-1}\), then this says that if \(P_{k+1}\) is a \((k+1)\)-parameter subset of \(P_{m+v}\) which is \(V'_1\)-crossing but not \(V'_i\)-crossing for any \(i > 1\), then the (old) color of \(P_{k+1}\) is determined by its signature with respect to \(V'_1, \ldots, V'_m\). On the other hand, since \(P_{v_1 + m}\) is \((V'_1, \ldots, V'_{m-1})\)-colored, any \(P_{k+1} \subseteq P_{m+v} \subseteq P_{m+v_1}\), such that \(P_{k+1}\) is \(V'_1\)-crossing for some \(i > 1\) (i.e., \(V'_{i-1}\)-crossing), has its (old) color determined only by its signature. Thus \(P_{m+v}\), with partition \(\{S'_0, S'_1, \ldots, S'_v, V'_1, V'_2, \ldots, V'_m\}\), is \((V'_1, \ldots, V'_m)\)-colored, and the lemma is proved.

We are now ready to complete the proof of the induction step for the case of \(B = A\).

Let \(v = \max_{x \in \{A, B, H, k + 1, r, t_1, \ldots, t_{r-1}, \ldots, t_r\}} N(A, B, H, k + 1, r, t_1, \ldots, t_{r-1}, \ldots, t_r), \quad z = (v^{v'})\), \quad m = N(A, B, H, 0, r_1, 1, 1, 1, 1, 1)\), and let \(v_1, v_2, \ldots, v_m\) be as previously defined. Then we assert that it is sufficient to choose \(N(A, B, H, k + 1, r, t_1, \ldots, t_r) = v_m\).

To prove this, let \(P_{v_m} \subseteq A^m\) be a \(v_m\)-parameter subset of \(A^m\), and suppose all the \((k+1)\)-parameter subsets of \(P_{v_m}\) are \(r\)-colored. By Lemma 2, there is an \((m+v)\)-parameter subset of \(P_{v_m} = P_{m+v}\)

\[
\begin{array}{c|c|c|c|c|c}
S_0 & S_1 & S_v & V_1 & V_m \\
\hline
[b \cdots \delta \pi_1 \cdots \delta_1 & \cdots & \pi_v \cdots \delta_0 & \tau_1 \cdots \eta_2 & \cdots & \tau_m \cdots \eta_m]
\end{array}
\]

which is \((V'_1, \ldots, V'_m)\)-colored.
We consider the $v$-parameter subsets of $P_{m+v}$ defined by

$$
\begin{array}{ccc}
S_0' & S_1' = S_1 & S_v' = S_v \\
S_0 & V_1 & V_m \\
\end{array}
$$

$$
P_v(i_1, \ldots, i_m) = [\tilde{b} \cdots \tilde{c} \ a_1^{i_1} \cdots a_1^{i_1} \cdots a_m^{i_1} \cdots a_m^{i_1} \ \ p_1 \cdots \delta_1 \ \ p_v \cdots \delta_v].
$$

Let $P_{k+1}$ and $P'_{k+1}$ be $(k+1)$-parameter subsets with $P_{k+1} \subseteq P_v(i_1, \ldots, i_m)$ and $P'_{k+1} \subseteq P_v(j_1, \ldots, j_m)$. We say $P_{k+1}$ and $P'_{k+1}$ are associated with respect to $(V_1, \ldots, V_m)$ if they are of the form

$$
\begin{array}{ccc}
S_0'' & S_1'' & S_{k+1}'' \\
S_0 & V_1 & V_m \\
\end{array}
$$

$$
P_{k+1} = [\tilde{b} \cdots \tilde{c} \ a_1^{i_1} \cdots a_m^{i_1} \ \ p' \cdots \delta']
$$

and

$$
\begin{array}{ccc}
S_0' & S_1' & S_{k+1}' \\
S_0 & V_1 & V_m \\
\end{array}
$$

$$
P'_{k+1} = [\tilde{b} \cdots \tilde{c} \ a_1^{j_1} \cdots a_m^{j_1} \ \ p' \cdots \delta']
$$

(i.e., $P'_{k+1}$ differs from $P_{k+1}$ only in that $i_1, \ldots, i_m$ have been replaced by $j_1, \ldots, j_m$ respectively, and everything else is unchanged).

A $v$-parameter subset of $P_{m+v}$ has some number of $(k+1)$-parameter subsets, which is at most $z = (a^{m+1})$. The $r$-coloring of $(k+1)$-parameter subsets induces a coloring of the $P_v(i_1, \ldots, i_m)$ (with at most $r^z$ colors) as follows: two such sets $P_v(i_1, \ldots, i_m)$ and $P_v(j_1, \ldots, j_m)$ have the same color if and only if each pair of associated $(k+1)$-parameter subsets $P_{k+1} \subseteq P_v(i_1, \ldots, i_m)$ and $P'_{k+1} \subseteq P_v(j_1, \ldots, j_m)$ have the same color.

Now let $P_m$ be the following $m$-parameter subset of $P_{m+v}$:

$$
\begin{array}{ccc}
S_0'' & S_1'' = V_1 & S_m'' = V_m \\
S_0 & S_1 & S_v \\
\end{array}
$$

$$
P_m = [\tilde{b} \cdots \tilde{c} \ a_1^{i_1} \cdots a_1^{i_1} \cdots a_m^{i_1} \cdots a_m^{i_1} \ \ \tau_1 \cdots \eta_1 \ \ \tau_m \cdots \eta_m].
$$

Each of the $t^m$ subsets $P_v(i_1, \ldots, i_m)$ contains exactly one point of $P_m$, and this clearly exhausts the $t^m$ points of $P_m$. Color the points of $P_m$ according to the rule that $P_m \cap P_v(i_1, \ldots, i_m)$ and $P_m \cap P_v(j_1, \ldots, j_m)$ have the same color if and only
if $P_u(i_1, \ldots, i_m)$ and $P_u(j_1, \ldots, j_m)$ have the same color. Thus, the 0-parameter sets of $P_m$ are $r^m$-colored.

Now by the theorem for the case $k=0$, $t_1 = \cdots = t_r = 1$ (which we have not yet proved) and the choice of $m$, $P_m$ contains a one-parameter set $P_1$,

$$
\begin{array}{c|c|c|c|c}
S_{0}^m & V_i & S_{1}^m \\
\hline
\hline
S_{0}^m & V_j
\end{array}
$$

$$
P_1 = [\bar{b} \cdots \bar{a}_i^0 \bar{a}_j^0 \cdots \bar{a}_i^m \cdots \sigma \tau_1 \cdots \sigma \eta_i \cdots],
$$

such that all of its 0-parameter subsets have the same color. Then by the construction of this coloring, the $(v+1)$-parameter subset $P_{v+1}$,

$$
\begin{array}{c|c|c|c|c}
S_{0}^{(v+1)} & S_{1}^{(v+1)} & S_{0}^{(v)} = S_{1}^{(v)} & S_{0}^{(v+1)} = S_{1}^{(v+1)} \\
\hline
\hline
S_{0} & V_{i}
\end{array}
$$

$$
P_{v+1} = [\bar{b} \cdots \bar{c} \bar{a}_i^0 \cdots \bar{a}_i^v \cdots \pi_1 \cdots \delta_1 \cdots \pi_v \cdots \delta_v \bar{a}_i^{v+1} \cdots \bar{a}_i^{v+m}],
$$

has the property that all of the $t$ $P_u(i_1, \ldots, i_m)$ contained in it have the same color. Let these be called $P_{v+1}^i, \ldots, P_{v+1}^t$. These are $S_{1}^{v+1}$-translates of each other.

By the definition of the coloring of the $P_u(i_1, \ldots, i_m)$, this means that if $P_{k+1}^i$ is any $(k+1)$-parameter subset of $P_v^i$ for some $j$, and if $P_{k+2}$ is its $S_{1}^{v+1}$-expansion, then $P_{k+1}^i = P_{k+2} \cap P_v^i$ all have the same color, $1 \leq i \leq t$.

Since $P_{v+1} \subseteq P_{m+v}$, and all the $S_{1}^{v+1}$-crossing $(k+1)$-parameter subsets have the same signature with respect to $(V_1, \ldots, V_m)$, then all these $(k+1)$-parameter subsets have the same color, say color $j$. By choice of $v$, $P_{v}^i$ has either a $t_1$-parameter subset all of whose $(k+1)$-parameter subsets have color 1, or a $t_2$-parameter subset all of whose $(k+1)$-parameter subsets have color 2, or ..., or a $(t_{j-1})$-parameter subset all of whose $(k+1)$-parameter subsets have color $j$, or ..., or a $t_r$-parameter subset all of whose $(k+1)$-parameter subsets have color $r$.

Suppose $P_{t_1-1}$ is a $(t_1-1)$-parameter subset of $P_v^i$ with all its $(k+1)$-parameter subsets having color $j$. Let $P_{t}$ be the $S_{1}^{v+1}$-expansion of $P_{t_1-1}$. Then all the $(k+1)$-parameter subsets of $P_{t} \cap P_v^i$ have color $j$, $1 \leq i \leq t$. Since $P_{t_1} \subseteq P_{v+1}$, all the $S_{1}^{v+1}$-crossing $(k+1)$-parameter subsets also have color $j$. By Remark 3, this accounts for all $(k+1)$-parameter subsets of $P_{t}$. So $P_{t}$ is a $t_r$-parameter subset of $P_{v+1} \subseteq P_{v+m}$ all of whose $(k+1)$-parameter subsets have color $j$. The alternative to this is the existence of a $t_r$-parameter subset of $P_{v} \subseteq P_{v+1} \subseteq P_{m+v}$ all of whose $(k+1)$-parameter subsets have color $i$, $i \neq j$. This is precisely what we wished to obtain, and the induction step is completed for $B=A$.

**Lemma 3.** *If the theorem is true for $A$, $B=A$, $H$ and integers $y, r, t_1, \ldots, t_r$, then it is true for $A$, $B$, $H$, $y, r, t_1, \ldots, t_r$, where $B$ is any nonempty subset of $A$.***
Proof. Let $\emptyset \neq B \subseteq A$. For each integer $x$ we say that an $x$-parameter subset $P(A, \bar{A}, H, \Pi, f, n, x)$ is of type A, and that $P(A, \bar{B}, H, \Pi, f, n, x)$ is of type B. Let $b$ be some fixed arbitrary element of $B$. Then if

$$P_x = [a \cdot \cdot \cdot d \pi \cdot \cdot \cdot x \cdot \cdot \cdot d]$$

is an $x$-parameter subset of type A, we can associate with it an $x$-parameter subset of type B, namely

$$P'_x = [b \cdot \cdot \cdot a \pi \cdot \cdot \cdot x \cdot \cdot \cdot d].$$

Now if all the $y$-parameter subsets of type B are $r$-colored, then this induces an $r$-coloring of the $y$-parameter subsets of type A by the rule that a subset $P_y$ of type A gets the same color as $P'_y$, which is of type B.

If the theorem is true for subsets of type A, then for $n$ sufficiently large we can find for some $i$ a $t_i$-parameter subset (of type A), $P_{t_i}$, all of whose $y$-parameter subsets have color $i$. Then $P'_{t_i}$ is a $t_i$-parameter subset of type B. All of its $y$-parameter subsets are of the form $P'_y$ where $P_y$ is a $y$-parameter subset of $P_{t_i}$. Thus $P'_{t_i}$ is the desired subset. This proves the lemma. (See essentially the same argument in [11].)

With this lemma the induction step of the theorem is completed. The entire proof will be completed when we establish the case $k=0$. To do this some notation and a preliminary lemma are needed. We shall write elements $(a_{i_1}, a_{i_2}, \ldots, a_{i_n}) \in A^n$ in the form $(a_{i_{a_1}} a_{i_{a_2}} \cdot \cdot \cdot a_{i_{a_n}})$, i.e., without commas. Further, we shall denote certain blocks of consecutive entries of an $n$-tuple by a single symbol, e.g., $(X_1 a_{i_1} X_2 a_{i_2} \cdot \cdot \cdot a_{i_r} X_{r+1})$, where each $X_k = x_{k1} x_{k2} \cdot \cdot \cdot x_{k_{n_k}} \in A^{n_k}$ for some $n_k$ (possibly $n_k = 0$, in which case $X_k$ is empty).

**Lemma 4.** Let $A = \{a_1, \ldots, a_l\}$ be a finite set with $l \geq 1$. Then for any positive integer $r$ there exists an integer $N(r, t)$ such that if $n \geq N(r, t)$ and the elements of $A^n$ are $r$-colored, then we can find a set of $t$ elements of $A^n$ of the form

$$X(i) = (X_1 a_{i_1} X_2 a_{i_2} \cdot \cdot \cdot a_{i_r} X_{r+1}), \quad 1 \leq i \leq t,$$

where $d \geq 2$ (i.e., the variable $a_i$ occurs at least once in $X(i)$), all of which have the same color.

**Proof.** A proof of this result can be found in [5]. The proof we give is direct and more in the spirit of the preceding arguments. The proof proceeds by induction on $t$. The theorem holds for $t=1$ and any $r$ by taking $N(r, 1) = 1$. Assume that for some $t \geq 2$ the lemma has been proved for all values of $|A| < t$. Let $A = \{a_1, \ldots, a_l\}$,
$A' = A - \{a_i\}$, and suppose the elements of $A^n$ are $r$-colored where $n \geq c_r + c_{r-1} + \cdots + c_1$ with

\[
\begin{align*}
    c_r &= N(r, t-1), \\
    c_{r-1} &= N(r^{c_r}, t-1), \\
    c_{r-2} &= N(r^{c_r + c_{r-1}}), t-1), \\
    &\vdots \\
    c_k &= N(r^{c_r + \cdots + c_k+1}), t-1), \\
    &\vdots \\
    c_1 &= N(r^{c_r + \cdots + c_2}, t-1).
\end{align*}
\]

Write $A^n$ as $A^{c_r + \cdots + c_2} \times A^{n-(c_r + \cdots + c_2)}$. The original $r$-coloring of $A^n$ induces an $r^{c_r + \cdots + c_2}$-coloring of $A^{n-(c_r + \cdots + c_2)}$ as follows: For $x, y \in A^{n-(c_r + \cdots + c_2)}$, $x$ and $y$ have the same "new" color iff for each point $z \in A^{c_r + \cdots + c_2}$, $\{z\} \times \{x\}$ and $\{z\} \times \{y\}$ have the same original color. This in turn determines an $r^{c_r + \cdots + c_2}$-coloring of $(A')^{n-(c_r + \cdots + c_2)}$. Since

\[
n - (c_r + \cdots + c_2) \geq c_1 = N(r^{c_r + \cdots + c_2}, t-1)
\]

then by the induction hypothesis there exist $t-1$ points of $(A')^{n-(c_r + \cdots + c_2)}$,

\[
X_1(i) = (X_{11}a_i, X_{12}a_1, \ldots, a_1 X_{1d_1}), \quad 1 \leq i < t,
\]

all of which have the same "new" color. By the definition of the "new" colors, for any choice of $Y \in A^{c_r + \cdots + c_2}$, all the $t-1$ points $Y \times X_1(i) \in A^n$, $1 \leq i < t$, have the same original color.

Next, writing $A^{c_r + \cdots + c_2} \times \{X_1(1)\}$ as $A^{c_r + \cdots + c_2} \times A^{c_2} \times \{X_1(1)\}$, the original $r$-coloring of $A^n$ induces an $r^{c_2 + \cdots + c_2}$-coloring of $A^{c_2}$ as follows: For $x, y \in A^{c_2}$, $x$ and $y$ have the same "newer" color iff for each point $z \in A^{c_r + \cdots + c_2}$, $\{z\} \times \{x\} \times X_1(1)$ and $\{z\} \times \{y\} \times X_1(1)$ have the same original color. As before, this determines an $r^{c_2 + \cdots + c_2}$-coloring of $(A')^{c_2} \subseteq A^{c_2}$. Since

\[
c_2 = N(r^{c_2 + \cdots + c_2}, t-1),
\]

then, by the induction hypothesis, there exist $t-1$ points of $(A')^{c_2}$,

\[
X_2(i) = (X_{21}a_i, X_{22}a_1, \ldots, a_1 X_{2d_2}), \quad 1 \leq i < t,
\]

all of which have the same "newer" color. By the definition of the "newer" colors, for any choice of $Y \in A^{c_r + \cdots + c_2}$, all the $t-1$ points $Y \times X_2(i_2) \times X_1(1)$, $1 \leq i_2 < t$, have the same original color. Hence, all the $(t-1)^2$ points $Y \times X_2(i_2) \times X_1(i_1)$, $1 \leq i_1, i_2 < t$, have the same color.

In general, repeating this procedure, we obtain at the $k$th step

\[
X_k(i) = (X_{k1}a_i, X_{k2}a_1, \ldots, a_1 X_{kd_k}), \quad 1 \leq i < t,
\]
where $X_k(i) \in A^n$. For any choice of $Y \in A^{x_1 + \cdots + x_{k+1}}$, all the $(t-1)^k$ points in $A^n$ of the form

$$Y \times X_k(i_k) \times \cdots \times X_2(i_2) \times X_1(i_1), \quad 1 \leq i_1, i_2, \ldots, i_k < t,$$

have the same original color. Finally, taking $k=r$ (in which case $Y$ is empty), we consider the $t^r$ points of $A^n$,

$$X_r(j_r) \times \cdots \times X_2(j_2) \times X_1(j_1), \quad 1 \leq j_r \leq t, \ 1 \leq k \leq r.$$

These have the property that for each $u$ the original color of the point

$$(5) \quad X_u(j_u) \times \cdots \times X_{u+1}(j_{u+1}) \times X_u(i_u) \times \cdots \times X_1(i_1)$$

is independent of the choice of $i_k$ for $1 \leq i_k < t$. The set of $r+1$ points

$$X_u = X_r(t) \times \cdots \times X_{u+1}(t) \times X_u(1) \times \cdots \times X_1(1), \quad 0 \leq u \leq r,$$

must contain a pair of points with the same color (by the pigeon-hole principle!), say $X_h$ and $X_{h'}$, $h > h'$. Finally, consider the $t$ points

$$X(i) = X_r(t) \times \cdots \times X_{h+1}(t) \times X_h(i) \times \cdots \times X_{h+1}(1) \times X_h(1) \times \cdots \times X_1(1), \quad 1 \leq i \leq t.$$

For $1 \leq i < t$, all the points $X(i)$ have the same color as that of $X_h$ (by (5)). On the other hand, $X(t) = X_{h'}$ which by the choice of $h'$ has the same color as that of $X_h$. Thus, all the points $X(i)$, $1 \leq i \leq t$, have the same color. We have shown that the lemma holds for the choice $N(r, t) = c_r + c_{r-1} + \cdots + c_1$. This completes the proof of the induction step and the lemma is proved.

We extend this special case to the complete statement of the theorem for $k=0$ in several steps, which follow.

Suppose now that $t \geq 2$ and $l \geq 1$. We can apply the preceding lemma to the set $A^l$ instead of $A$ in a straightforward manner to obtain the result that if $n \geq ln(r, t^l)$ and the points of $A^n$ are $r$-colored, then there exists a set of $t^l$ points of the form

$$(X_1a_1a_2 \cdots a_l, X_2a_1a_2 \cdots a_l, \ldots a_1a_2 \cdots a_lX_d) \in A^n,$$

$1 \leq i_1, i_2, \ldots, i_l \leq t$, all of which have the same color.

The reader will notice that this set of $t^l$ points is nothing other than an $l$-parameter set $P_l = P(A, B, H, \Pi, f, n, l)$ in $A^n$ with $H = \{e\}$, $B = A$ (i.e., all constant maps are allowed) and $\Pi$ and $f$ appropriately defined. Further, the 0-parameter subsets of $P_l$ are just the points of $P_l$, so that $P_l$ has all its 0-parameter sets the same color.

We immediately extend the result to the case where $B$ is not necessarily equal to $A$ by invoking Lemma 3 with $y=0$. 
Next, the extension to an arbitrary permutation group $H: A \rightarrow A$ (instead of $H = \{e\}$) is immediate since the choice of $H$ does not affect the 0-parameter subsets of an $l$-parameter set (which always has just $|B|^l$ 0-parameter subsets).

Finally, we must consider the situation in which the initial $n$-parameter set $A^n$ is replaced by a fixed arbitrary $n$-parameter set $P_n$ in $A^n$ (for some fixed $w$). This is immediate, however, since the obvious map from the points of $P_n$ to the points of $A^n$ induces a one-to-one map on their respective $k$-parameter subsets, for each $k$, and preserves inclusion both ways.

Thus, we have seen that if $n \geq lN(r, t)$, and the 0-parameter subsets of an $n$-parameter set $P_n \subseteq A^n$ (for some fixed $w$) are $r$-colored, then there exists an $l$-parameter set $P_l$ in $P_n$ such that all the 0-parameter subsets of $P_l$ have one color. This is just the statement of the case $k = 0$, $t_1 = \cdots = t_r = l$, which, since $l$ is arbitrary, clearly implies the theorem for $k = 0$. With this fact, the proof of the theorem is completed.

8. Consequences of the theorem. In this section we present several corollaries to the theorem, the most well known of these being the theorems of van der Waerden (Corollary 8) and of Ramsey (Corollary 11). Other corollaries are new, in particular, the results for affine and vector spaces, which we present first.

**Corollary 1.** Let $l, r$ be positive integers, $F = GF(q)$ a finite field and $k = 0$ or 1. Then there is an integer $N = N(q, r, l, k)$ depending only on $q, r, l, k$, with the following property: If $A$ is an affine space over $F$ of dimension $n \geq N$, and if all the $k$-dimensional affine subspaces of $A$ are $r$-colored in any way, then there is some $l$-dimensional affine subspace of $A$ with all of its $k$-dimensional affine subspaces having one color.

**Proof.** We prove this by applying the theorem to the case in which $A = GF(q) = \{0, 1, a_0, \ldots, a_{q-1}\}, B = A, t_1 = t_2 = \cdots = t_r = l$, and

$$H = \{\sigma : \text{for some } a, b \in F, a \neq 0, \text{ and all } y \in F, \sigma : y \rightarrow ay+b\},$$

the affine group. All we need to show here is that all $x$-parameter subsets are $x$-dimensional affine subspaces of $A^n = F^n$, and that for $k = 0$ or 1, all the $k$-dimensional affine subspaces are in fact $k$-parameter subsets. For once we know this, we can apply the theorem with $n \geq N(A, B, H, k, r, t_1, \ldots, t_r) = N(q, r, l, k)$ to deduce the desired result. Thus, if an $l$-parameter set has all its $k$-parameter sets one color, this is actually an $l$-dimensional affine subspace with all of its $k$-dimensional affine subspaces having one color, as required.

First, then, let

$$P_x = [\bar{a} \cdots \bar{b} \quad \pi_1 \cdots \delta_1 \quad \cdots \quad \pi_x \cdots \delta_x].$$
Suppose that for all $y \in F$ we have
\[
\begin{align*}
y^a_1 &= c_1y + a_1, \\
y^a_2 &= d_1y + b_1, \\
\vdots \\
y^a_x &= c_xy + a_x, \\
y^a_x &= d_xy + b_x.
\end{align*}
\]
Define $x+1$ vectors as follows:
\[
\begin{array}{cccc}
S_0 & S_1 & S_x \\
v_0 &= (a_1, \ldots, b, a_1, \ldots, b, \ldots, a_x, \ldots, b_x) \\
S_0 & S_1 & S_x \\
v_1 &= (0, \ldots, 0, c_1, \ldots, d_1, 0, \ldots, 0, \ldots, 0) \\
\vdots \\
S_0 & S_1 & S_{x-1} & S_x \\
v_x &= (0, \ldots, 0, 0, \ldots, 0, \ldots, 0, c_x, \ldots, d_x).
\end{array}
\]
Then
\[
P_x = \{v_0 + \alpha_1v_1 + \cdots + \alpha_xv_x : \alpha_1, \ldots, \alpha_x \in F\},
\]
an $x$-dimensional affine subspace of $F^n$.

Now any $n$-tuple, or point, of $F^n$ is both a 0-dimensional affine subspace and a 0-parameter subset, since $B = A = F$ here. Thus all 0-dimensional affine subspaces are 0-parameter sets.

Finally, let $A_1$ be a 1-dimensional affine subspace of $F^n$. Then for some vectors $u = (u_1, \ldots, u_n)$ and $v = (v_1, \ldots, v_0)$, $A_1 = \{u + \alpha v : \alpha \in F\}$. Let $S_2 = \{i_1, \ldots, i_q\} = \{i : v_i \neq 0\}$, and $S_0 = \{j_1, \ldots, j_h\} = \{i : v_i = 0\}$. Then
\[
S_0 & S_1 \\
A_1 = [u_1 \cdots u_n \ pi_1 \cdots pi_q]
\]
where the maps $\pi_i$ are defined, for $i \in S_1$, by $\pi_i : x \rightarrow v_ix + u_i$. Hence $A_1$ is a 1-parameter subset of $F^n$. Thus, all 1-dimensional affine subspaces are 1-parameter sets. This completes the proof of the corollary.

**Corollary 2.** Let $l$, $r$, be positive integers, $F = GF(q)$ a finite field and $k = 0$ or 1. Then there is a number $N' = N'(q, r, l, k)$, depending only on $q$, $r$, $l$, and $k$, with the following property: If $V$ is an $n$-dimensional vector space over $F$ with $n \geq N'$, and if the $k$-dimensional vector subspaces of $V$ are $r$-colored in any way, then there is an $l$-dimensional vector subspace of $V$ with all of its $k$-dimensional vector subspaces having one color.
Proof. We prove this by applying the theorem to the case where \( A = F, B = \{0\}, t_1 = t_2 = \cdots = t_r = l, \) and \( H = \{\sigma:\text{for some } a \neq 0 \text{ in } F, \sigma = ay \text{ for all } y \in F\}, \) the multiplicative group of \( F. \) Again, what we have to show is that any \( x \)-parameter set is an \( x \)-dimensional subspace, and that any 0- or 1-dimensional subspace is a 0- or 1-parameter set, respectively. As before, we can then apply the theorem with \( n \geq N(A, B, H, k, r, t_1, \ldots, t_l) = N(q, r, l, k) \) to obtain the required result. Let \( P_x \) be an \( x \)-parameter set. Then

\[
P_x = [0 \ 0 \ \cdots \ 0 \ \pi_1 \ \cdots \ \delta_1 \ \cdots \ \pi_x \ \cdots \ \delta_x].
\]

Suppose

\[
y^{\pi_1} = c_1 y,
\]

\[
\vdots
\]

\[
y^{\pi_x} = c_x y,
\]

\[
\vdots
\]

\[
y^{\delta_x} = d_x y.
\]

Let \( x \) vectors be defined by

\[
v_1 = (0, \ldots, 0, c_1, \ldots, d_1, 0, \ldots, 0, \ldots, 0, 0, \ldots, 0)
\]

\[
\vdots
\]

\[
v_x = (0, \ldots, 0, 0, \ldots, 0, \ldots, 0, \pi_1, \ldots, \pi_x).
\]

Then \( P_x = \{a_1 v_1 + \cdots + a_x v_x : a_1, \ldots, a_x \in F\}. \) So \( P_x \) is an \( x \)-dimensional vector subspace.

There is only one 0-dimensional subspace of \( V, \) namely \( \{0, 0, \ldots, 0\}, \) and this is a 0-parameter subset. If \( V_1 \) is a 1-dimensional subspace, then for some vector \( (v_1, \ldots, v_n), \) \( V_1 = \{a(v_1, \ldots, v_n) : a \in F\}. \) Let \( S_1 = \{i_1, \ldots, i_g\} = \{i : v_i \neq 0\}, \) and \( S_0 = \{1, 2, \ldots, n\} - S_1. \) Then

\[
V_1 = [0 \ 0 \ \cdots 0 \ \pi_{i_1} \ \cdots \ \pi_{i_g}],
\]

\( \pi_i : x \to v_i x \) for all \( x \in F, \) and \( V_1 \) is a 1-parameter set. Thus all 1-dimensional subspaces are 1-parameter sets, and the corollary is proved.

**Remark.** The last corollary (Rota’s conjecture for \( k = 0, 1 \)) is also true for \( k = 2. \) This result is not a direct corollary of the theorem, but follows from Corollary 1 by an inductive argument which can be found in [3], [11]. That argument, in fact, shows that if the affine statement is true for some fixed \( k, \) and all \( q, r, l, \) then Rota’s conjecture is true for \( k + 1, \) and all \( q, r, l. \)
We have established the affine analogue to Ramsey's Theorem for the 0- and 1-dimensional cases \((k=0, 1)\) in Corollary 1 above by choosing objects \(A, B\) and \(H\) appropriately and applying the theorem to the resulting \(n\)-parameter sets. These same choices, however, do not yield the corresponding higher dimensional cases \((k \geq 2)\) of the affine analogue. What we obtain instead is a theorem about some but not all of the affine subspaces of an affine space. We illustrate with an example.

Let \(A\) be the field of two elements, \(B=A\), and \(H\) the affine group defined in the proof of Corollary 1. Then, as we observed in the proof of Corollary 1, the 0-parameter subsets of \(A^n\) are precisely the 0-dimensional affine subspaces of \(A^n\), and the 1-parameter subsets of \(A^n\) are precisely the 1-dimensional affine subspaces of \(A^n\). Furthermore, all the \(k\)-parameter subsets of \(A^n\), even for \(k \geq 2\), are \(k\)-dimensional affine subspaces of \(A^n\). The difficulty in extending the results arises from the fact that not all of the \(k\)-dimensional affine subspaces, \(k \geq 2\), are \(k\)-parameter subsets.

Consider, for example, the 2-dimensional affine subspace of \(A^n\) defined by \(S=\{(1, 1, 0, \ldots, 0) + \beta(0, 1, 1, 0, \ldots, 0) : \alpha, \beta \in A\}\). This has four points in it: \((0, 1, 1, 0, \ldots, 0), (1, 1, 0, 0, \ldots, 0), (1, 0, 1, 0, \ldots, 0), (0, 0, 0, 0, \ldots, 0)\). It is clear that there is no way to partition the coordinates so that these four points can be represented in the usual way as a 2-parameter subset.

The trouble in the 2-dimensional case illustrated by this example is common to all the higher dimensional cases over all fields. Namely, our concept of \(k\)-parameter set requires a partitioning of the coordinates of \(A^n\) into \(k+1\) disjoint subsets, whereas a basis for a \(k\)-dimensional subspace need not arise from such a partition. This problem also arises in the projective analogue. The disjointness of the coordinates in the "parameters," \(S_i\), was essential in the induction step of the proof of the theorem. Any overlapping of the \(S_i\) would require some sort of rule for combining the overlapping entries, which in turn would have to be consistent with a similar rule in the \(*\)-sets, where overlapping would also occur.

**Corollary 3.** Given integers \(l\) and \(r\), there exists an integer \(N(l, r)\) such that if \(S\) is a finite set with \(|S| \geq N(l, r)\) and the subsets of \(S\) are \(r\)-colored, then there exist \(l\) disjoint nonempty subsets \(S_1, \ldots, S_l\) of \(S\) such that all \(2^l-1\) unions \(\bigcup_{i \in J} S_i, \emptyset \neq J \subseteq \{1, 2, \ldots, l\}\), have one color.

**Proof.** In the theorem, let \(A=\{0, 1\}, B=\{0\}, H=\{e\}, k=1, t_1=t_2=\cdots=t_r=l\) and \(P_n=A^n\). Then we conclude that if \(n \geq N(A, B, H, k, r, t_1, \ldots, t_r) = N(l, r)\), and if the 1-parameter sets in \(A^n\) are \(r\)-colored, then there exists an \(l\)-parameter set \(P_l\) in \(A^n\) all of whose 1-parameter subsets have one color. Let \(S=\{1, 2, \ldots, n\}\), and with each nonempty subset \(X \subseteq S\) associate an element \(h(X)=(a_1, \ldots, a_n) \in A^n\) in the following way:

\[
a_i = 1 \quad \text{if} \quad i \in X,
\]

\[
a_i = 0 \quad \text{otherwise}.
\]
Note that not all the $a_i$ are 0. However, with each nonzero point $(a_1, \ldots, a_n) \in A^n$ we can associate the 1-parameter set $\{(0, 0, \ldots, 0), (a_1, a_2, \ldots, a_n)\}$ in $A^n$. Hence, any $r$-coloring of the nonempty subsets of $S$ induces a natural $r$-coloring of the 1-parameter subsets of $A^n$. Since $n \geq N(l, r)$ then, as mentioned at the beginning of the proof, there exists an $l$-parameter set $P_l$ in $A^n$ all of whose 1-parameter sets have one color. Let $\Pi = \{S_0, S_1, \ldots, S_l\}$ be the partition of $\{1, 2, \ldots, n\}$ associated with $P_l$. The important fact to notice here is that not only is $h(S_i) \in P_l$ for any $i > 0$, but, in fact, by the definition of an $l$-parameter set, $h(X) \in P_l$ for any $X = \bigcup_{j \in J} S_j$, $\emptyset \neq J \subseteq \{1, 2, \ldots, l\}$. Thus, all $2^l - 1$ of the subsets $\bigcup_{j \in J} S_j$, $\emptyset \neq J \subseteq \{1, 2, \ldots, l\}$, correspond to the 1-parameter subsets of $P_l$ which by the conclusion of the theorem all have one color. Finally, since the color of any 1-parameter set in $A^n$ was just that of its associated subset of $S$, then all the subsets $\bigcup_{j \in J} S_j$, $\emptyset \neq J \subseteq \{1, 2, \ldots, l\}$, have the same color. This proves the corollary.

**Corollary 4** (J. Folkman [1], R. Rado [9], J. Sanders [13]). Given integers $l$ and $r$, there exists an integer $N'(l, r)$ such that if $n \geq N'(l, r)$ and the positive integers $\leq n$ are $r$-colored then there exist $l$ integers $a_1, \ldots, a_l$ such that all the sums $\{\sum_{i=1}^{l} a_i : e_i = 0 \text{ or } 1, \text{ not all } e_i = 0\}$ have one color.

**Proof.** Let $h$ map the binary $n$-tuples $x = (x_1, \ldots, x_n) \in \{0, 1\}^n$ into the integers by $h(x) = \sum_{i=1}^{l} x_i 2^{i-1}$. A direct application of Corollary 3 with $n \geq N'(l, r) = 2^{N(0,r)}$ shows that for any $r$-coloring of the binary $n$-tuples (i.e., integers $\leq 2^n$) we can find $l$ binary $n$-tuples (i.e., $l$ integers) $x^{(1)}, \ldots, x^{(l)}$ such that $x^{(i)}_j x^{(j)}_k = 0$ for all $i, j$ and $k$ (i.e., the powers of 2 used in the dyadic expansions of $h(x^{(1)}), \ldots, h(x^{(l)})$ are all distinct) and all $2^l - 1$ componentwise sums $\{\sum_{i \in J} x^{(i)} : \emptyset \neq J \subseteq \{1, 2, \ldots, l\}\}$ (i.e., all $2^l - 1$ sums $\{\sum_{i=1}^{l} e_i h(x^{(i)}) : e_i = 0 \text{ or } 1, \text{ not all } e_i = 0\}$) have the same color. This proves the corollary.

The case $l=2$ of Corollary 4 was first proved by Schur [14]. Corollary 4 is actually a special case of Corollary 6 below.

**Corollary 5.** Given integers $l, r$, there exists an integer $N''(l, r)$ such that if $G$ is any group with $|G| \geq N''(l, r)$, and if the elements of $G$ are $r$-colored, then there exist $l$ elements $a_1, \ldots, a_l$ in $G$ such that all the products $a_i a_{i_2} \cdots a_{i_l}$ have one color for all $j \geq 1$ and all choices of distinct $i_1, \ldots, i_j$ in $\{1, 2, \ldots, l\}$.

**Proof.** For each finite group $G$ let $A(G)$ be the size of the largest abelian subgroup of $G$. Let $m(n) = \min_{|G| = n} A(G)$. Then it is known [6] that $m(n) \to \infty$ as $n \to \infty$. That is, every large group has a large abelian subgroup. Thus it is sufficient to establish Corollary 5 for abelian groups.

Let $A$ be an abelian group of order at least $(N'(l, r) - 1)^{N(l, r) - 1} + 1$, where $N(l, r)$ is the number guaranteed in Corollary 3 above, and $N'(l, r)$ is from Corollary 4. Let the elements of $A$ be $r$-colored. Since $A$ is the product of cyclic groups, say $A = Z_{i_1} \times \cdots \times Z_{i_l}$, where $i_j$ is the order of $Z_{i_j}$, then either $M \geq N(l, r)$ or $i_j \geq N'(l, r)$ for some $i_j$. In this latter case we can apply Corollary 4 to the cyclic group $Z_{i_j}$ of order $i_j$ and obtain $l$ elements $a_1, \ldots, a_l$, satisfying the conclusion of Corollary 5.
On the other hand, suppose $M \geq N(l, r)$. Let $g_1, \ldots, g_M$ be the generators respectively of the cyclic subgroups $Z_{1i}, \ldots, Z_{1m}$. We associate with each subset of $\{g_i : 1 \leq i \leq M\}$ the color of the product of its members. By Corollary 3 there must be $l$ disjoint subsets whose unions all have the same color. This means that there are $l$ products $h$, $1 \leq j \leq l$, of the $g_i$, no two with a common factor, such that all the products $h_{j1} \cdot \cdot \cdot h_{jk}$, for $1 \leq k \leq l$ and for any choice of the $j_1, \ldots, j_k$, have the same color. This completes the proof of Corollary 5.

It is interesting to note that the corresponding result for finite semigroups is false. For consider the semigroup $S$ with $n$ elements, including 0, such that $ab = 0$ for all $a, b \in S$. Then if we color 0 one color and all the other elements of $S$ another color, we clearly cannot find even two elements $a, b$ such that $a, b$ and $ab$ are all the same color.

**Corollary 6.** Let $L=L(x_1, \ldots, x_m)$, $1 \leq i \leq h$, be a system of homogeneous linear equations with real coefficients with the property that for each $j$, $1 \leq j \leq m$, there exists a solution $(e_1, \ldots, e_m)$ to the system $L$ with $e_j = 0$ or 1 and $e_j = 1$. Then given an integer $r$ there exists an integer $N(r)$ such that if $n \geq N(r)$ and the positive integers $< n$ are $r$-colored, then $L$ can be solved with integers having one color.

**Proof.** Let $E_i=(e_{i1}, e_{i2}, \ldots, e_{im})$, $1 \leq i \leq m$, be solutions to the system $L$ with $e_{ij} = 0$ or 1 and $e_{ij} = 1$. As in Corollary 4 we choose $N(r) = 2^{N(m, r)}$. For $n \geq N(r)$ any $r$-coloring of the positive integers $< n$ induces a coloring of the (nonzero) binary $N(m, r)$-tuples of $\{0, 1\}^{N(m, r)}$, which, by the arguments of the preceding corollaries and the choice of $n$, implies that there exists an $m$-parameter set $P_m$ with $A = \{0, 1\}$, $B = \{0\}$, $H = \{e\}$ and such that all $2^m - 1$ nonzero points of $P_m$ have one color. Thus, the points $c_i$ given by

$$
\begin{array}{cccc}
S_0 & S_1 & S_2 & S_m \\
\hline
0, \ldots, 0, e_{i1}, \ldots, e_{i1}, \ldots, e_{ij}, \ldots, e_{ij}, \ldots, e_{im}, \ldots, e_{im}
\end{array}
$$

for $1 \leq i \leq m$, all have the same color. As before, reinterpreting these $n$-tuples as integers written to the base 2, the hypothesis that $L$ is homogeneous and linear together with the definition of the $e_{ij}$ show that $(c_1, \ldots, c_m)$ is a monochromatic solution of $L$. This proves the corollary.

Corollary 6 is similar to the important results of R. Rado [8].

By a multigrade of order $m$ we mean two disjoint sets of integers $\{c_i : 1 \leq i \leq n\}, \{d_i : 1 \leq i \leq m\}$ such that

$$
\sum_{i=1}^{n} c_i^k = \sum_{i=1}^{m} d_i^k \quad \text{for } k = 1, 2, \ldots, m.
$$

This is denoted by

$$
c_1, \ldots, c_n \sim d_1, \ldots, d_m.
$$
Since \( \{ac_i + b : 1 \leq i \leq n\}, \{ad_i + b : 1 \leq i \leq n\} \) is a multigrade of order \( m \) if \( \{c_i : 1 \leq i \leq n\}, \{d_i : 1 \leq i \leq n\} \) is, then a straightforward application of the theorem along the lines used in the preceding corollaries yields

**Corollary 7.** If the multigrade equations

\[
(*) \quad x_1, \ldots, x_n \equiv y_1, \ldots, y_n
\]

have any integer solution (which always happens, for example, if \( n \geq 2^m - 1 \)), then for any \( r \)-coloring of the positive integers, \((*)\) always has a solution in integers having one color.

**Corollary 8 (Van der Waerden [6], [14]).** Given integers \( t \) and \( r \), there exists an integer \( M(t, r) \) such that if \( n \geq M(t, r) \) and the nonnegative integers \(< n \) are arbitrarily \( r \)-colored, then there must exist a monochromatic arithmetic progression of length \( t \).

**Proof.** We apply the theorem to the case \( A = \{0, 1, \ldots, t-1\}, B = A, H = \{e\}, k = 0, t_1 = \cdots = t_r = 1 \) and \( P_n = A^n \). Let \( N = N(A, \overline{B}, H, k, r, t_1, \ldots, t_r) \), let \( M(t, r) = t^N \) and choose \( n \geq M(t, r) \). By writing any integer \( j, 0 \leq j < M(t, r) \) in the form \( j = \sum_{i=0}^{r-1} c_i t^i, 0 \leq c_i < t \) (i.e., to the base \( t \)), we have a one-to-one correspondence between the integers \( j, 0 \leq j < M(t, r) \), and elements of \( A^n \) given by \( j \leftrightarrow (c_{j_0}, \ldots, c_{j_{n-1}}) \).

Hence, an \( r \)-coloring of the integers \( \{0, 1, \ldots, n-1\} \) induces an \( r \)-coloring of the elements of \( A^n \) (where we ignore the integers \( \geq M(t, r) \)). Since all these elements of \( A^n \) are 0-parameter sets of \( A^n \) then by the choice of \( N \), the theorem guarantees the existence of a 1-parameter set

\[
P_1 = [\overline{\bar{a} \cdots \bar{b} \pi_1, \ldots, \delta_i}] = [\overline{\bar{a} \cdots \bar{b} e \cdots e}]
\]

\[
\begin{array}{cccc}
S_0 & S_1 \\
\begin{bmatrix}
  a & \cdots & b & 0 & \cdots & 0 \\
  a & \cdots & b & 1 & \cdots & 1 \\
  a & \cdots & b & t-1 & \cdots & t-1
\end{bmatrix} & \begin{bmatrix}
  (a, \ldots, b, & 0 & , \ldots, & 0) \\
  (a, \ldots, b, & 1 & , \ldots, & 1) \\
  (a, \ldots, b, & t-1 & , \ldots, & t-1)
\end{bmatrix}
\end{array}
\]

all of whose 0-parameter sets (=points) have one color. But the \( t \) points of \( P_1 \) (shown above) certainly correspond to \( t \) integers which lie in an arithmetic progression (since \( S_1 \neq \emptyset \)). This proves the corollary.

This result is implied by the stronger

**Corollary 9 (Hales-Jewett [5]).** Let \( A = \{a_1, \ldots, a_t\} \) be a finite set. Given an integer \( r \) there exists an integer \( N(r, t) \) such that if \( n \geq N(r, t) \) and the set \( A^n \) is \( r \)-colored then there exists a set of \( t \) elements of \( A^n \) of the form

\[
X_t = (x_{1t}, \ldots, x_{1n}, a_t, x_{2t}, \ldots, x_{2n}, a_t, \ldots, a_t, x_{nt}, \ldots, x_{nt}) \in A^n, \quad 1 \leq i \leq t,
\]

all of which have the same color.
Proof. This result is a special case of the theorem in which $A = \{a_1, \ldots, a_i\}$, $B = A$, $H = \{e\}$, $k = 0$ and $t_1 = \cdots = t_i = 1$ (also, see Lemma 3).

We remark that the elegant derivation of van der Waerden’s Theorem from Corollary 9 given in [5] is essentially different from the one given here.

The next corollary is a Ramsey theorem for partitions of a finite set with the ordering on the partitions inverted from the usual ordering. For the usual ordering ($\Pi \leq \Pi'$ if $\Pi$ is a refinement of $\Pi'$) a Ramsey theorem is trivially true:

For integers $k, l, r$, and any $r$-coloring of the partitions of any sufficiently large set $S$, $|S| = n$, there is a partition $\Pi$ with $n - l$ blocks with all partitions $\Pi' \leq \Pi$ with $n - k$ blocks having the same color.

The proof is simply the observation that the lattice of refinements of the partition $\Pi$: $\{1, 2\}, \{3, 4\}, \ldots, \{2m - 1, 2m\}, \{2m + 1\}, \{2m + 2\}, \ldots, \{n\}$ is isomorphic to the lattice of subsets of a set of $m$ elements, and is a lower ideal in the lattice of partitions of $S$. Then Ramsey’s Theorem (for subsets) can be invoked.

For the inverted ordering, we define $\Pi' \leq \Pi$ if $\Pi$ is a refinement of $\Pi'$.

Corollary 10. Given integers $k, l, r$, there exists an integer $M(k, l, r)$ such that if $n \geq M(k, l, r)$, and the partitions of a set of $n$ elements into $k$ blocks are $r$-colored, then there is a partition into $l$ blocks, $\Pi$, with all partitions $\Pi' \leq \Pi$ with $k$ blocks having the same color.

Proof. Let $A = \{0, 1\}$, $B = \{0\}$, $H = \{e\}$. Let $S_0 = \{1\}, S_1 = \{2\}, \ldots, S_{n-1} = \{n\}$, and let

$$P_{n-1} = \begin{bmatrix} S_0 & S_1 & \cdots & S_{n-1} \\ 0 & e & \cdots & e \end{bmatrix}.$$ 

By the choice of $A$, $B$ and $H$, the $x$-parameter subsets of $P_{n-1}$ are determined exactly by their corresponding partitions $\Pi$. The subset $P_x$ with partition $\Pi$, is contained in the subset $P_n$, with partition $\Pi'$ if and only if $\Pi \leq \Pi'$. Thus, applying the theorem to this case produces the desired result. We just let

$$M(k, l, r) = N(A, B, H, k-1, r, l-1, \ldots, l-1) + 1.$$ 

We remark that these results on partitions of sets have analogues for partitions of integers which can be derived from the above by associating each set with its cardinality.

Corollary 11 (Ramsey’s Theorem). Given positive integers $k, l, r$ there exists an integer $N_1 = N_1(k, l, r)$ such that if $n \geq N_1$ and the $k$-subsets of an $n$-set $M_n$ are $r$-colored, then all the $k$-subsets of some $l$-set $M_l \leq M_n$ have the same color.

Proof. As in Corollary 10, let $A = \{0, 1\}$, $B = \{0\}$ and $H = \{e\}$. Let $N_1 = N_1(k, l, r) = N(A, B, H, k, r, l, \ldots, l)$ of the theorem. It is sufficient to establish the result for the set $X = \{1, 2, \ldots, N_1\}$. Assume the $k$-subsets of $X$ have been $r$-colored. This induces an $r$-coloring of the $k$-parameter subsets of the $N_1$-parameter set $A^{N_1}$ as
follows: For a $k$-parameter subset $P_k \subseteq A^N_i$ with partition $\Pi = \{S_0, S_1, \ldots, S_k\}$ let $m_i$ denote the minimal element of $S_i$, $1 \leq i \leq k$, and let $M_k = \{m_1, m_2, \ldots, m_k\}$; assign to $P_k$ the color of the $k$-set $M_k$. This is a well-defined coloring of all the $k$-parameter subsets of $A^N_i$. By the definition of $N_i$, there exists an $l$-parameter set $P_l$ of all its $k$-parameter subsets having the same color. In particular, if the partition for $P_l$ is $\Pi_l' = \{T_{i_0}, T_{i_1}, \ldots, T_{i_k}\}$ and $M_k = \{m'_1, \ldots, m'_l\}$ where $m'_i$ is the minimal element of $T_{i_i}$, then for any $k$-subset $M_k = \{m'_1, \ldots, m'_k\} \subseteq M_k$, the color of $M_k$ is the same as the color of the $k$-parameter subset $P_k \subseteq P_l$ which has partition $\Pi = \{T_{i_0}^*, \ldots, T_{i_k}^*\}$ with $T_{i_k}^* = \{1, 2, \ldots, N_i\} \cap \bigcup_{i=1}^{k} T_{i_i}$. Since all of these $P_k$ have the same color, then all $k$-subsets of $M_k$ have the same color and the corollary is proved.

We conclude with a final (stronger) application of the theorem.

Let $C_n = \{(x_1, \ldots, x_n) : x_i = 0 \text{ or } 1\}$ be the set of $2^n$ vertices of a unit $n$-cube in $\mathbb{R}^n$. Let us call a subset $Q_k \subseteq C_n$ a $k$-subspace of $C_n$ if $|Q_k| = 2^k$ and $Q_k$ is contained in some $k$-dimensional euclidean subspace of $\mathbb{R}^n$.

**Corollary 12.** Given integers $k, l, r$, there exists an integer $N(k, l, r)$ such that if $n \geq N(k, l, r)$ and the $k$-subspaces of $C_n$ are $r$-colored, then there exists an $l$-subspace of $C_n$ all of whose $k$-subspaces have one color.

**Proof.** We first establish a preliminary result. Let $P_k$ denote a $k$-dimensional (euclidean) subspace of $\mathbb{R}^n$ and let $T_k = P_k \cap C_n$. Then we assert

$$|T_k| \leq 2^k$$

and if $|T_k| = 2^k$, then $T_k$ is a $k$-parameter subset of $C_n$ with $A = B = \{0, 1\}$, and $H = \{e, \pi\}$ is the group of order 2. To prove this, write $P_k$ as

$$P_k = \langle \alpha_1 X_1 + \cdots + \alpha_k X_k + X_0 : \alpha_i \in \mathbb{R} \rangle$$

where the $X_1, \ldots, X_k$ are linearly independent vectors in $\mathbb{R}^n$, and $X_0 \in \mathbb{R}^n$.

Consider the $j$th component of a point of $T_k$. It is either 0 or 1. Thus one of the following two equations must hold:

$$\alpha_1 x_{1j} + \cdots + \alpha_k x_{kj} + x_{0j} = 0,$$

$$\alpha_1 x_{1j} + \cdots + \alpha_k x_{kj} + x_{0j} = 1.$$

Hence, the only possible $\alpha_i$'s for $T_k$ must lie on one of the two parallel hyperplanes determined by these equations. We have such a pair of equations for each $j = 1, 2, \ldots, n$. The hyperplanes have directions (in pairs) respectively:

$$X_{11}, \ldots, X_{k1},$$

$$X_{12}, \ldots, X_{k2},$$

$$\vdots$$

$$X_{1n}, \ldots, X_{kn}.$$

But by assumption, the columns $X_1, \ldots, X_k$ are independent.
Therefore we can find \( k \) independent rows, say, for example, rows 1, 2, \ldots, \( k \), and consequently the corresponding matrix

\[
\begin{pmatrix}
x_{11}, \ldots, x_{k1} \\
\vdots \\
x_{1k}, \ldots, x_{kk}
\end{pmatrix}
\]

is nonsingular. Thus, for each set of equations

\[
x_{11}a_1 + \cdots + x_{k1}a_k = e_1 - x_{01}, \\
\vdots \\
x_{k1}a_1 + \cdots + x_{kk}a_k = e_k - x_{0k}, \quad e_i = 0 \text{ or } 1,
\]

there is exactly one choice for the \( a_i \)'s satisfying them. Since the \( a_i \)'s determine the points of \( T_k \), and since there are at most \( 2^k \) possible choices for the \( e_i \), we have at most \( 2^k \) possibilities for the \( a_i \)'s. Furthermore, the only way we get all \( 2^k \) is when all \( 2^k \) possibilities for the \( e_i \)'s occur. In this case \((|T_k| = 2^k)\), we have \( 2^k - 1 \) solutions with \( e_1 = 0 \), and \( 2^k - 1 \) solutions with \( e_1 = 1 \). If \( e_2, \ldots, e_k \) are fixed, and we look at the two solutions from \( e_1 = 0 \) and \( e_1 = 1 \), then these two solutions differ by a vector \( v = (v_1, \ldots, v_k) \) which is independent of \( e_2, \ldots, e_k \). In particular, \( (v_1, \ldots, v_k) \) must satisfy

\[
x_{11}v_1 + \cdots + x_{k1}v_k = 1, \\
x_{12}v_1 + \cdots + x_{k2}v_k = 0, \\
\vdots \\
x_{1k}v_1 + \cdots + x_{kk}v_k = 0.
\]

\( v \) is thus uniquely determined by the \( x_i \)'s independent of the \( e_i \)'s. Certainly, if \( \alpha = (a_1, \ldots, a_k) \) is a solution for \( e_1 = 0 \) and some \( e_2, \ldots, e_k \), then \( \alpha + v \) is a solution for the same \( e_2, \ldots, e_k \) with \( e_1 = 1 \).

This means that for each point \( p \) in \( T_k \) with \( e_1 = 0 \), there is a point \( q \) in \( T_k \) with \( e_1 = 1 \) such that

\[
q = p + (v_1X_1 + \cdots + v_kX_k) = p + U_1.
\]

Since \( q \) and \( p \) have all entries 0 and 1, \( U_1 \) must have all entries 0, 1 and \(-1\). In fact, repeating this argument with \( e_2, \ldots, e_k \) replacing \( e_1 \), we obtain a set of vectors \( U_1, U_2, \ldots, U_k \), with entries 0, 1, \(-1\), and the point \( P_0 \) with \( e_1 = e_2 = \cdots = e_k = 0 \) such that

\[
T_k = \{ P_0 + e_1U_1 + \cdots + e_kU_k : e_i = 0, 1 \}.
\]

No two of the \( U_i \) can have a nonzero entry in the same coordinate, or else there would be three values occurring there, violating the fact that all points of \( T_k \) have only entries of 0 and 1.

If \( U_i \) has a \(-1\) entry in, say, the \( h \)th position, then \( U_j \) has a 0 in the \( h \)th position for \( j \neq i \), and \( P_0 \) must have a +1 in the \( h \)th position, in order to insure entries of 0 and 1 in \( T_k \).
$T_k$ is a $k$-parameter set, then, with $A = B = \{0, 1\}$ and $H = \{e, \pi\}$ the group of order 2. We can write $T_k$ as

$$T_k = [a \cdots b \pi_1 \cdots \delta_k]$$

$$= \begin{bmatrix} a \cdots b & 0 & 0 & \cdots & 11 & \cdots & 00 & \cdots & 11 \\ a \cdots b & 11 & 00 & \cdots & 11 & \cdots & 11 & \cdots & 00 \end{bmatrix}. $$

$S_0$ consists of those coordinates $j$ for which every $U_i$ is 0; the value $f(j)$ (where $j$ is the function required in the definition of a $k$-parameter set) for $j \in S_0$ is 0 or 1 according to the corresponding entry in $P_0$. Each $S_i, i > 0$, consists of those $j$ for which $U_i$ has a nonzero $j$th component; the value $f(j)$ for $j \in S_i$ is $e$ if the component is 1 and $\pi$ if the component is $-1$. This proves (6) and the assertion which follows it.

The proof of the corollary now follows at once from the theorem by choosing $A = B = \{0, 1\}, H = \{e, \pi\}, t_1 = \cdots = t_l = 1,$ and $N(k, l, r) = N(A, B, H, k, r, t_1, \ldots, t_l)$.

We point out that even though the techniques of the proof of the theorem are constructive so that upper bounds on the various $N$'s of the corollaries can be given, these bounds are usually enormous, to say the least. To illustrate this, we consider the first nontrivial case of Corollary 12, the determination of an upper bound on $N(1, 2, 2)$. We recall that by definition $N(1, 2, 2)$ is an integer such that if $n \geq N(1, 2, 2)$ and the $(\binom{2k}{2l})$ straight line segments joining all possible pairs of vertices of a unit $n$-cube are arbitrarily 2-colored, then there always exists a set of four coplanar vertices which determines six line segments of the same color. Let $N^*$ denote the least possible value $N(1, 2, 2)$ can assume. We introduce a calibration function $F(m, n)$ with which we may compare our estimate of $N^*$. This is defined recursively as follows:

$$F(1, n) = 2^n, \quad F(m, 2) = 4, \quad m \geq 1, n \geq 2,$$

$$F(m, n) = F(m-1, F(m, n-1)), \quad m \geq 2, n \geq 3. $$

It is recommended that the reader calculate a few small values of $F$ to get a feeling for its rate of growth, e.g., $F(5, 5)$ or $F(10, 3)$.

If the bounds generated by the recursive constructions needed for the proof of Corollary 12 are explicitly tabulated, the best estimate for $N^*$ we obtain this way is roughly

$$N^* \leq F(F(F(F(F(F(12, 3), 3), 3), 3), 3), 3), 3).$$

On the other hand, it is known only that $N^* \geq 6$. Clearly, there is some room for improvement here.

9. **Concluding remarks.** We conclude with several questions.

(i) In the corollaries of the theorem listed, we never really make much use of the
freedom we have in choosing $B$ and $H$. What are some interesting applications for some less trivial choices of $B$ and $H$?

(ii) Are the various infinite versions of certain of the corollaries valid? A specific simple case would be: If the positive integers are 2-colored, is it true that there always exists an infinite subset $A$ such that all sums $\sum_{b \in B} b$, $\emptyset \neq B \subseteq A$, $B$-finite, have one color?

(iii) With respect to the corollaries, the upper bounds given by the theorem on the various $N$’s are rather crude, as has been pointed out. Is it possible to improve significantly the estimates of these numbers? For example, in Corollary 12, the upper bound on $N(1, 2, 2)$ given by the theorem is truly enormous, where, in fact, the exact bound is probably $<10$.

(iv) It was suggested by M. Simonovits that perhaps it would be possible to give an intrinsic definition of $k$-parameter sets, i.e., one which does not depend on coordinates. If this is possible then conceivably the corresponding proofs might become simpler.

(v) Our particular definition of a $k$-parameter set was chosen, to a certain extent, because a Ramsey theorem for them could be proved. What other definitions will have this property? In particular, can a suitable one be found which will establish Rota’s original conjecture for $k$-subspaces of finite vector space, $k \geq 3$?
