

THE AUGMENTED BASE LOCUS IN POSITIVE CHARACTERISTIC

PAOLO CASCINI, JAMES M^CKERNAN, AND MIRCEA MUSTAŢĂ

To Slava Shokurov, with admiration, on the occasion of his sixtieth birthday

ABSTRACT. Let L be a nef line bundle on a projective scheme X in positive characteristic. We prove that the augmented base locus of L is equal to the union of the irreducible closed subsets V of X such that $L|_V$ is not big. For a smooth variety in characteristic zero, this was proved by Nakamaye using vanishing theorems.

1. INTRODUCTION

Let X be a projective scheme over an algebraically closed field k , and L a line bundle on X . The base locus $\text{Bs}(L)$ of L is the closed subset of X consisting of those $x \in X$ such that every section of L vanishes at x . It is easy to see that if m_1 and m_2 are positive integers such that m_1 divides m_2 , then $\text{Bs}(L^{m_2}) \subseteq \text{Bs}(L^{m_1})$. It follows from the Noetherian property that $\text{Bs}(L^m)$ is independent of m if m is divisible enough; this is the *stable base locus* $\mathbf{SB}(L)$ of L .

The stable base locus is a very interesting geometric invariant of L , but it is quite subtle: for example, there are numerically equivalent Cartier divisors whose stable base loci are different. Nakamaye introduced in [5] the following upper approximation of $\mathbf{SB}(L)$, the *augmented base locus* $\mathbf{B}_+(L)$. If $L \in \text{Pic}(X)$ and $A \in \text{Pic}(X)$ is ample, then

$$\mathbf{B}_+(L) := \mathbf{SB}(L^m \otimes A^{-1}),$$

for $m \gg 0$. It is easy to check that this is well-defined, it is independent of A , and only depends on the numerical equivalence class of L . The following is our main result.

Theorem 1.1. *Let X be a projective scheme over an algebraically closed field of positive characteristic. If L is a nef line bundle on X , then $\mathbf{B}_+(L)$ is equal to L^\perp , the union of all irreducible closed subsets V of X such that $L|_V$ is not big.*

We note that since L is nef, for an irreducible closed subset V of X , the restriction $L|_V$ is not big if and only if V has positive dimension and $(L|_V^{\dim(V)}) = 0$. When X is a smooth projective variety in characteristic zero, the above theorem was proved in [5], making use of the Kawamata-Viehweg vanishing theorem. It is an interesting question whether the result holds in characteristic zero when the variety is singular.

Key words and phrases. Stable base locus, augmented base locus, big and nef line bundle.

The proof of Theorem 1.1 makes use in an essential way of the Frobenius morphism. The following is a key ingredient in the proof.

Theorem 1.2. *Let X be a projective scheme over an algebraically closed field of positive characteristic. If L is a nef line bundle on X and D is an effective Cartier divisor such that $L(-D)$ is ample, then $\mathbf{B}_+(L) = \mathbf{B}_+(L|_D)$.*

In the proofs of the above results we make use of techniques introduced by Keel in [2]. In fact, if we replace in Theorem 1.2 the two augmented base loci by the corresponding stable base loci, we recover one of the main results in [2]. We give a somewhat simplified proof of this result (see Corollary 3.6 below), and this proof extends to give also Theorem 1.2.

In the next section we recall some basic facts about augmented base loci. The proofs of Theorems 1.2 and 1.1 are then given in §3.

1.1. **Acknowledgment.** We are indebted to Rob Lazarsfeld for discussions that led to some of the results in this paper. We would also like to thank Seán Keel for several very useful discussions and the referee for some useful comments.

2. AUGMENTED BASE LOCI AND BIG LINE BUNDLES

In this section we review some basic facts about the augmented base locus. This notion is usually defined for integral schemes. However, even if one is only interested in this restrictive setting, for the proof of Theorem 1.1 we need to also consider possibly reducible, or even non-reduced schemes. We therefore define the augmented base locus in the more general setting that we will need. Its general properties follow as in the case of integral schemes, for which we refer to [1].

Let X be a projective scheme over an algebraically closed field k . If L is a line bundle on X and $s \in H^0(X, L)$, then we denote by $Z(s)$ the zero-locus of s (with the obvious scheme structure). Note that $Z(s)$ is defined by a locally principal ideal, but in general it is not an effective Cartier divisor (if X is reduced, then $Z(s)$ is an effective Cartier divisor if and only if no irreducible component of X is contained in $Z(s)$). The base locus of L is by definition the closed subset of X given by

$$\mathrm{Bs}(L) := \bigcap_{s \in H^0(X, L)} Z(s)_{\mathrm{red}}.$$

If m is a positive integer and $s \in H^0(X, L)$, then it is clear that $Z(s)_{\mathrm{red}} = Z(s^{\otimes m})_{\mathrm{red}}$, hence $\mathrm{Bs}(L^m) \subseteq \mathrm{Bs}(L)$. More generally, we have $\mathrm{Bs}(L^{mr}) \subseteq \mathrm{Bs}(L^r)$ for every $m, r \geq 1$, hence by the Noetherian property there is $m_0 \geq 1$ such that

$$\mathbf{SB}(L) := \bigcap_{r \geq 1} \mathrm{Bs}(L^r)$$

is equal to $\mathrm{Bs}(L^m)$ whenever m is divisible by m_0 . The closed subset $\mathbf{SB}(L)$ of X is the *stable base locus* of L . It follows by definition that $\mathbf{SB}(L) = \mathbf{SB}(L^r)$ for every $r \geq 1$.

Since X is projective, every line bundle is of the form $\mathcal{O}_X(D)$, for some Cartier divisor D (see [4]). We will sometimes find it convenient to work with Cartier divisors, rather than line bundles. Let $\text{Cart}(X)_{\mathbf{Q}} := \text{Cart}(X) \otimes_{\mathbf{Z}} \mathbf{Q}$ denote the group of Cartier \mathbf{Q} -divisors and $\text{Pic}(X)_{\mathbf{Q}} := \text{Pic}(X) \otimes_{\mathbf{Z}} \mathbf{Q}$. For a Cartier divisor D , we put $\mathbf{SB}(D) = \mathbf{SB}(\mathcal{O}_X(D))$. Since $\mathbf{SB}(D) = \mathbf{SB}(rD)$ for every $r \geq 1$, the definition extends in the obvious way to $\text{Cart}(X)_{\mathbf{Q}}$.

Given a Cartier \mathbf{Q} -divisor D , the augmented base locus of D is

$$\mathbf{B}_+(D) := \bigcap_A \mathbf{SB}(D - A),$$

where the intersection is over all ample Cartier \mathbf{Q} -divisors on X . It is easy to see that if A_1 and A_2 are ample Cartier \mathbf{Q} -divisors such that $A_1 - A_2$ is ample, then $\mathbf{SB}(D - A_2) \subseteq \mathbf{SB}(D - A_1)$. It follows from the Noetherian property that there is an ample Cartier \mathbf{Q} -divisor A such that $\mathbf{B}_+(D) = \mathbf{SB}(D - A)$. Furthermore, in this case if A' is ample and $A - A'$ is ample, too, then $\mathbf{B}_+(D) = \mathbf{SB}(D - A')$. It is then clear that if H is any ample Cartier divisor on X , then for $m \gg 0$ we have

$$\mathbf{B}_+(D) = \mathbf{SB}\left(D - \frac{1}{m}H\right) = \mathbf{SB}(mD - H).$$

The following properties of the augmented base locus are direct consequences of the definition (see [1, §1]).

- 1) For every Cartier \mathbf{Q} -divisor D , we have $\mathbf{SB}(D) \subseteq \mathbf{B}_+(D)$.
- 2) If D_1 and D_2 are numerically equivalent Cartier \mathbf{Q} -divisors, then $\mathbf{B}_+(D_1) = \mathbf{B}_+(D_2)$.

If D is a Cartier divisor and $L = \mathcal{O}_X(D)$, we also write $\mathbf{B}_+(L)$ for $\mathbf{B}_+(D)$.

Lemma 2.1. *If L is a line bundle on the projective scheme X , and Y is a closed subscheme of X , then*

- i) $\mathbf{SB}(L|_Y) \subseteq \mathbf{SB}(L)$.
- ii) $\mathbf{B}_+(L|_Y) \subseteq \mathbf{B}_+(L)$.

Proof. The first assertion follows from the fact that if $s \in H^0(X, L)$, then $Z(s|_Y) \subseteq Z(s)$, hence $\text{Bs}(L^m|_Y) \subseteq \text{Bs}(L^m)$ for every $m \geq 1$. For the second assertion, fix an ample line bundle A on X , and let $m \gg 0$ be such that $\mathbf{B}_+(L) = \mathbf{SB}(L^m \otimes A^{-1})$. Since $A|_Y$ is ample on Y , using i) and the definition of the augmented base locus of $L|_Y$, we obtain

$$\mathbf{B}_+(L|_Y) \subseteq \mathbf{SB}(L^m|_Y \otimes A^{-1}|_Y) \subseteq \mathbf{SB}(L^m \otimes A^{-1}) = \mathbf{B}_+(L).$$

□

Recall that a line bundle L on an integral n -dimensional scheme X is *big* if there is $C > 0$ such that $h^0(X, L^m) \geq Cm^n$ for $m \gg 0$. Equivalently, this is the case if and only if there are Cartier divisors A and E , with A ample and E effective, such that $L^m \simeq \mathcal{O}_X(A + E)$ for some $m \geq 1$. We refer to [3, §2.2] for basic facts about big line

bundles on integral schemes. The following lemma is well-known, but we include a proof for completeness.

Lemma 2.2. *Let X be an n -dimensional projective scheme and L a line bundle on X . For every coherent sheaf \mathcal{F} on X , there is $C > 0$ such that $h^0(X, \mathcal{F} \otimes L^m) \leq Cm^n$ for every $m \geq 1$.*

Proof. Let us write $L \simeq A \otimes B^{-1}$ for suitable very ample line bundles A and B . For every $m \geq 1$, the line bundle B^m is very ample. By choosing a section $s_m \in H^0(X, B^m)$ such that $Z(s_m)$ does not contain any of the associated subvarieties of \mathcal{F} , we obtain an inclusion $H^0(X, \mathcal{F} \otimes L^m) \hookrightarrow H^0(X, \mathcal{F} \otimes A^m)$. Since $h^0(X, \mathcal{F} \otimes A^m) = P(m)$ for $m \gg 0$, where P is a polynomial of degree $\leq n$, we obtain the assertion in the lemma. \square

If X is reduced, and A, D are Cartier divisors on X with A ample and D effective, then the restriction of $\mathcal{O}_X(A+D)$ to every irreducible component Y of X is big (note that the restriction $D|_Y$ is well-defined and gives an effective divisor on Y). As a consequence of the next lemma, we will obtain a converse to this statement.

Lemma 2.3. *Let X be a reduced projective scheme. Given line bundles L and A on X , with A ample, if $m \gg 0$ and $s \in H^0(X, L^m \otimes A^{-1})$ is general, then for every irreducible component Y of X such that $L|_Y$ is big, we have $Y \not\subseteq Z(s)$.*

Note that since A is ample, if $s \in H^0(X, L^m \otimes A^{-1})$ and Y' is an irreducible component of X (considered with the reduced scheme structure) such that $L|_{Y'}$ is not big, then $Y' \subseteq Z(s)$.

Proof of Lemma 2.3. Suppose that Y is an irreducible component of X (considered with the reduced structure) such that $L|_Y$ is big, but such that for infinitely many m we have $Y \subseteq Z(s)$ for every $s \in H^0(X, L^m \otimes A^{-1})$. If W is the union of the other irreducible components of X , also considered with the reduced scheme structure, then we have an exact sequence

$$0 \rightarrow \mathcal{O}_X \rightarrow \mathcal{O}_Y \oplus \mathcal{O}_W \rightarrow \mathcal{O}_{Y \cap W} \rightarrow 0,$$

where $Y \cap W$ denotes the (possibly non-reduced) scheme-theoretic intersection of Y and W . After tensoring with $L^m \otimes A^{-1}$ and taking global sections, this induces the exact sequence

$$\begin{aligned} 0 \rightarrow H^0(X, L^m \otimes A^{-1}) &\rightarrow H^0(Y, L^m \otimes A^{-1}|_Y) \oplus H^0(W, L^m \otimes A^{-1}|_W) \\ &\rightarrow H^0(Y \cap W, L^m \otimes A^{-1}|_{Y \cap W}). \end{aligned}$$

By assumption, the map $H^0(X, L^m \otimes A^{-1}) \rightarrow H^0(Y, L^m \otimes A^{-1}|_Y)$ is zero for infinitely many m , in which case the above exact sequence implies

$$(1) \quad h^0(Y, L^m \otimes A^{-1}|_Y) \leq h^0(T, L^m \otimes A^{-1}|_T).$$

Let $n = \dim(Y)$. Since $\dim(T) \leq n - 1$, it follows from Lemma 2.2 that we can find $C > 0$ such that

$$h^0(T, L^m \otimes A^{-1}|_T) \leq Cm^{n-1}$$

for all m . On the other hand, since $L|_Y$ is big, it is easy to see that there is $C' > 0$ such that $h^0(Y, L^m \otimes A^{-1}|_Y) \geq C'm^n$ for all $m \gg 0$. These two estimates contradict (1) when $m \gg 0$. \square

Corollary 2.4. *Let L be a line bundle on the reduced projective scheme X . If the restriction of L to every irreducible component of X is big, then for every ample line bundle A and every $m \gg 0$, the zero locus of a general section in $H^0(X, L^m \otimes A^{-1})$ defines an effective Cartier divisor on X .*

3. MAIN RESULTS

In this section we assume that all our schemes are of finite type over an algebraically closed field k of characteristic $p > 0$. For such a scheme X we denote by $F = F_X$ the absolute Frobenius morphism of X . This is the identity on the topological space, and it takes a section f of \mathcal{O}_X to f^p . Note that F is a finite morphism of schemes (not preserving the structure of schemes over k). We will also consider the iterates F^e of F , for $e \geq 1$.

Let us recall some basic facts concerning pull-back of line bundles, sections, and subschemes. Suppose that L is a line bundle on X and Z is a closed subscheme of X .

- 1) There is a canonical isomorphism of line bundles $(F^e)^*(L) \simeq L^{p^e}$.
- 2) The scheme-theoretic inverse image $Z^{[e]} := (F^e)^{-1}(Z)$ is a closed subscheme of X defined by the ideal $I_Z^{[p^e]}$, such that if I_Z is locally generated by $(f_i)_i$, then $I_Z^{[p^e]}$ is defined by $(f_i^{p^e})_i$. In particular, if Y is another closed subscheme of X , having the same support as Z , there is some e such that Y is a subscheme of $Z^{[e]}$.
- 3) If $s \in H^0(Z, L|_Z)$, then $(F^e)^*(s)$ is a section in $H^0(Z^{[e]}, (F^e)^*(L)|_{Z^{[e]}})$, whose restriction to Z gets identified with $s^{\otimes p^e} \in H^0(Z, L^{p^e}|_Z)$.

Lemma 3.1. *If X is a projective scheme over k and L is a line bundle on X , then*

- i) $\mathbf{SB}(L) = \mathbf{SB}(L|_{X_{\text{red}}})$.
- ii) $\mathbf{B}_+(L) = \mathbf{B}_+(L|_{X_{\text{red}}})$.

Proof. The inclusions “ \supseteq ” in both i) and ii) follow from Lemma 2.1. Let us prove the reverse implication in i). Let m be such that $\mathbf{SB}(L|_{X_{\text{red}}}) = \text{Bs}(L^m|_{X_{\text{red}}})$. Given $x \in X$, suppose that $x \notin \text{Bs}(L^m|_{X_{\text{red}}})$. Consider $s \in H^0(X_{\text{red}}, L^m|_{X_{\text{red}}})$ such that $x \notin Z(s)$. Let J denote the ideal defining X_{red} , and let $e \gg 0$ be such that $J^{[p^e]} = 0$. In this case $(F^e)^*(s)$ gives a section in $H^0(X, L^{mp^e})$ whose restriction to X_{red} is equal to $s^{\otimes p^e}$. In particular, $x \notin Z((F^e)^*(s))$. We conclude that $x \notin \text{Bs}(L^{mp^e})$, hence $x \notin \mathbf{SB}(L)$. This completes the proof of i).

Let A be an ample line bundle on X , and let $m \gg 0$ be such that $\mathbf{B}_+(L|_{X_{\text{red}}}) = \mathbf{SB}(L^m \otimes A^{-1}|_{X_{\text{red}}})$ and $\mathbf{B}_+(L) = \mathbf{SB}(L^m \otimes A^{-1})$. The assertion in ii) now follows by applying i) to $L^m \otimes A^{-1}$. \square

The following is a key result from [2]. We give a different proof, that has the advantage that it will apply also when replacing the stable base loci by the augmented base loci.

Theorem 3.2. *If L is a nef line bundle on a projective scheme X , and D is an effective Cartier divisor on X such that $L(-D)$ is ample, then*

$$\mathbf{SB}(L) = \mathbf{SB}(L|_D).$$

We isolate the key point in the argument in a lemma that we will use several times.

Lemma 3.3. *Let A be an ample line bundle on a projective scheme X , and D an effective Cartier divisor on X . If $L := A \otimes \mathcal{O}_X(D)$ is nef, then for every $m \geq 1$ and every section $s \in H^0(D, L^m|_D)$, there is $e \geq 1$ such that $s^{\otimes p^e} \in H^0(D, L^{mp^e}|_D)$ is the restriction of a section in $H^0(X, L^{mp^e})$.*

Proof. Consider the short exact sequence

$$0 \rightarrow L^m(-D) \rightarrow L^m \rightarrow L^m|_D \rightarrow 0.$$

Pulling-back by F^e gives the exact sequence

$$0 \rightarrow L^{mp^e}(-p^e D) \rightarrow L^{mp^e} \rightarrow L^{mp^e}|_{p^e D} \rightarrow 0.$$

Note that $L^m(-D) = L^{m-1} \otimes L(-D)$ is ample, since L is nef and $L(-D)$ is ample. By asymptotic Serre vanishing, we conclude that for $e \gg 0$ we have $H^1(X, L^{mp^e}(-p^e D)) = 0$, and therefore the restriction map

$$H^0(X, L^{mp^e}) \rightarrow H^0(X, L^{mp^e}|_{p^e D})$$

is surjective. Therefore there is $t \in H^0(X, L^{mp^e})$ such that $t|_{p^e D} = (F^e)^*(s)$. In this case the restriction of t to D is equal to $s^{\otimes p^e}$. \square

Proof of Theorem 3.2. It follows from Lemma 2.1 that it is enough to show that if P is a point on X that does not lie in $\mathbf{SB}(L|_D)$, then P does not lie in $\mathbf{SB}(L)$. If P does not lie on D , then it is clear that $P \notin \mathbf{SB}(L)$, since $A := L \otimes \mathcal{O}_X(-D)$ is ample. On the other hand, if $P \in D$, let $m \geq 1$ be such that there is a section $s \in H^0(D, L^m|_D)$, with $P \notin Z(s)$. Since $Z(s^{\otimes p^e})_{\text{red}} = Z(s)_{\text{red}}$, in order to show that $P \notin \mathbf{SB}(L)$ it is enough to show that for some e , the section $s^{\otimes p^e}$ lifts to a section in $H^0(X, L^{mp^e})$. This is a consequence of Lemma 3.3. \square

Corollary 3.4. *Let X be a reduced projective scheme. If L and A are line bundles on X , with A ample and L nef, and $Z = Z(s)$ for some $s \in H^0(X, L \otimes A^{-1})$, then $\mathbf{SB}(L) = \mathbf{SB}(L|_Z)$.*

Proof. Let X' be the union of the irreducible components of X that are contained in Z , and let X'' be the union of the other components (we consider on both X' and X'' the reduced scheme structures). If $X' = X$, then $Z = X$ and there is nothing to prove, while if $X' = \emptyset$, then Z is an effective Cartier divisor and the assertion follows from Theorem 3.2. Therefore we may and will assume that both X' and X'' are non-empty.

Using the fact that A is ample and the definition of the stable base locus, we obtain $\mathbf{SB}(L) \subseteq \mathbf{SB}(L \otimes A^{-1}) \subseteq Z$. As in the proof of Theorem 3.2, we see that it is enough to show that if $t \in H^0(Z, L^m|_Z)$ for some m , then there is $e \geq 1$ such that $t^{\otimes p^e}$ can be lifted to a section in $H^0(X, L^{mp^e})$. By applying Lemma 3.3 to X'' , $D = Z \cap X''$ and the ample line bundle $L|_{X''} \otimes \mathcal{O}_{X''}(-D)$, we see that for some e we can lift $t^{\otimes p^e}|_{X'' \cap Z}$ to a section $t'' \in H^0(X'', L^{mp^e}|_{X''})$. Since $X' \subseteq Z$, the restriction of t'' to $X'' \cap X'$ is equal to $t^{\otimes p^e}|_{X' \cap X''}$. Therefore we can glue $t^{\otimes p^e}|_{X'}$ with t'' to get a section in $H^0(X, L^{mp^e})$ lifting $t^{\otimes p^e}$. \square

Recall that if L is a nef line bundle on the projective scheme X , then the *exceptional locus* L^\perp is the union of all closed irreducible subsets $V \subseteq X$ such that $L|_V$ is not big. Since L is nef, this condition is equivalent to the fact that $\dim(V) > 0$ and $(L|_V^{\dim(V)}) = 0$.

Remark 3.5. It is easy to see by induction on $\dim(X)$ that L^\perp is a closed subset of X . Note first that if X_1, \dots, X_r are the irreducible components of X (with the reduced scheme structures), then clearly $L^\perp = (L|_{X_1})^\perp \cup \dots \cup (L|_{X_r})^\perp$. Therefore we may assume that X is integral. In this case, if L is not big, then $L^\perp = X$. Otherwise, we can find an effective Cartier divisor D and a positive integer m such that $L^m(-D)$ is ample. It is clear that if $L|_V$ is not big, then $V \subseteq D$. Therefore $L^\perp = (L|_D)^\perp$, hence it is closed by induction.

The following result is one of the main results from [2]. As we will see, this is an easy consequence of Corollary 3.4.

Corollary 3.6. *If L is a nef line bundle on the projective scheme X , then $\mathbf{SB}(L) = \mathbf{SB}(L|_{L^\perp})$.*

Proof. Arguing by Noetherian induction, we may assume that the result holds for every proper closed subscheme of X . Since $L^\perp = (L|_{X_{\text{red}}})^\perp$, it follows from Lemma 3.1 that we may assume that X is reduced. If the restriction of L to every irreducible component of X is not big, then $L^\perp = X$, and there is nothing to prove. From now on we assume that this is not the case, and let X' and X'' be the union of those irreducible components of X on which the restriction of L is not (respectively, is) big. On both X' and X'' we consider the reduced scheme structures. Note that by assumption X'' is nonempty.

Consider an ample line bundle A on X . It follows from Lemma 2.3 that if $m \gg 0$, there is a section $s \in H^0(X, L^m \otimes A^{-1})$ such that no irreducible component of X'' is contained in $Z = Z(s)$ (but such that $X' \subseteq Z$). It is clear that if V is an irreducible closed subset of X such that $L|_V$ is not big, then $V \subseteq Z$. Therefore $L^\perp = (L|_Z)^\perp$. Since X'' is nonempty, it follows that $Z \neq X$, hence the inductive assumption gives $\mathbf{SB}(L|_Z) = \mathbf{SB}(L|_{L^\perp})$. On the other hand, Corollary 3.4 gives

$$\mathbf{SB}(L) = \mathbf{SB}(L^m) = \mathbf{SB}(L^m|_Z) = \mathbf{SB}(L|_Z),$$

which completes the proof. \square

We can now prove the second theorem stated in the Introduction.

Proof of Theorem 1.2. We suitably modify the argument in the proof of Theorem 3.2. By Lemma 2.1, it is enough to prove the inclusion $\mathbf{B}_+(L) \subseteq \mathbf{B}_+(L|_D)$. Furthermore, Lemma 3.1 implies $\mathbf{B}_+(L|_D) = \mathbf{B}_+(L|_{2D}) = \mathbf{B}_+(L^2|_{2D})$ and we have $\mathbf{B}_+(L) = \mathbf{B}_+(L^2)$, hence we may replace L by L^2 and D by $2D$ to assume that $L(-D) \simeq A^2$, for some ample line bundle A .

Suppose that P is a point that does not lie on $\mathbf{B}_+(L|_D)$. If $P \notin D$, since $L(-D)$ is ample, it follows that $P \notin \mathbf{B}_+(L)$. Hence from now on we may assume that $P \in D$. By assumption, for $m \gg 0$ we have $P \notin \mathbf{SB}(L^m \otimes A^{-1}|_D)$. Let us choose $r \geq 1$ such that there is $t \in H^0(D, L^{rm} \otimes A^{-r}|_D)$ with $P \notin Z(t)$. Furthermore, since we may take r large enough, we may assume that $A^{r-1}|_D$ is globally generated. Let $t' \in H^0(D, A^{r-1}|_D)$ be such that $P \notin Z(t')$. Therefore $t \otimes t' \in H^0(D, L^{rm} \otimes A^{-1})$ is such that $P \notin Z(t \otimes t')$. Note that $L^{rm} \otimes A^{-1}(-D) \simeq L^{rm-1} \otimes A$ is ample, since L is nef and A is ample. Therefore Lemma 3.3 implies that for some $e \geq 1$, the section $t^{\otimes p^e} \otimes t'^{\otimes p^e}$ can be lifted to a section in $H^0(X, L^{rmp^e} \otimes A^{-p^e})$, and this section clearly does not vanish at P . This shows that $P \notin \mathbf{B}_+(L)$, and completes the proof of the theorem. \square

Corollary 3.7. *Let X be a reduced projective scheme. If L and A are line bundles on X , with L nef and A ample, and $Z = Z(s)$ for some $s \in H^0(X, L \otimes A^{-1})$, then $\mathbf{B}_+(L) = \mathbf{B}_+(L|_Z)$.*

Proof. We modify slightly the argument in the proof of Theorem 1.2, along the lines in the proof of Corollary 3.4. By Lemma 2.1, it is enough to show that if $P \notin \mathbf{B}_+(L|_Z)$, then $P \notin \mathbf{B}_+(L)$. Let X' be the union of the irreducible components of X that are contained in Z , and X'' the union of the other components, both considered with the reduced scheme structures. If $X' = X$, then $Z = X$ and there is nothing to prove, while if $X' = \emptyset$, then Z is an effective Cartier divisor, and the assertion follows from Theorem 1.2. From now on, we assume that both X' and X'' are nonempty.

After replacing L and A by L^2 and A^2 , respectively, and s by $s^{\otimes 2}$, we may assume that $A = B^2$, for some ample line bundle B (note that $\mathbf{B}_+(L|_{Z(s)}) = \mathbf{B}_+(L|_{Z(s^{\otimes 2})})$ by Lemma 3.1). Suppose that $P \notin \mathbf{B}_+(L|_Z)$. If $P \notin Z$, then $P \notin \mathbf{SB}(L \otimes A^{-1})$; since A is ample, we have $\mathbf{B}_+(L) \subseteq \mathbf{SB}(L \otimes A^{-1})$, hence $P \notin \mathbf{B}_+(L)$. From now on we assume that P lies in Z .

Arguing as in the proof of Theorem 1.2, we find a section

$$t \otimes t' \in H^0(Z, L^{rm} \otimes A^{-1}|_Z)$$

such that $P \notin Z(t \otimes t')$, and we use Lemma 3.3 to deduce that for some $e \geq 1$, we can lift $t^{\otimes p^e} \otimes t'^{\otimes p^e}|_{Z \cap X''}$ to a section $t'' \in H^0(X'', L^{rmp^e} \otimes A^{-p^e}|_{X''})$. Recall that $X' \subseteq Z$, hence $X' \cap X'' \subseteq Z \cap X''$, and therefore $t''|_{X' \cap X''} = t^{\otimes p^e} \otimes t'^{\otimes p^e}|_{X' \cap X''}$. Since X is reduced, it follows that we can glue t'' and $t^{\otimes p^e} \otimes t'^{\otimes p^e}|_{X'}$ to a section in $H^0(X, L^{rmp^e} \otimes A^{-p^e})$ that does not vanish at P . Therefore $P \notin \mathbf{B}_+(L)$, which concludes the proof. \square

We now give the proof of the characteristic p version of Nakamaye's theorem.

Proof of Theorem 1.1. We argue as in the proof of Corollary 3.6. By Noetherian induction, we may assume that the theorem holds for every proper closed subscheme of X . Lemma 3.1 implies $\mathbf{B}_+(L) = \mathbf{B}_+(L|_{X_{\text{red}}})$, and since $L^\perp = (L|_{X_{\text{red}}})^\perp$, we may assume that X is reduced.

Note that the inclusion $L^\perp \subseteq \mathbf{B}_+(L)$ is clear: if V is a closed irreducible subset of X that is not contained in $\mathbf{B}_+(L)$, then we can find an ample line bundle A , a positive integer m , and $s \in H^0(X, L^m \otimes A^{-1})$ such that $V \not\subseteq Z(s)$. Therefore $s|_V$ gives a nonzero section of $L^m \otimes A^{-1}|_V$, hence $L|_V$ is big. This shows that it is enough to prove the inclusion $\mathbf{B}_+(L) \subseteq L^\perp$.

If the restriction of L to all the irreducible components of X is not big, then $L^\perp = X$, and the assertion is clear. Otherwise, let X' denote the union of the irreducible components of X on which the restriction of L is not big, and X'' the union of the other components, both with the reduced scheme structures. It follows from Lemma 2.3 that given any ample line bundle A , we can find $m \geq 1$ and a section $s \in H^0(X, L^m \otimes A^{-1})$ whose restriction to every component of X'' is nonzero (and whose restriction to X' is zero). Let $Z = Z(s)$. By assumption X'' is nonempty, and therefore Z is a proper closed subscheme of X , hence by the inductive assumption we have $\mathbf{B}_+(L|_Z) = (L|_Z)^\perp$. If $V \subseteq X$ is an irreducible closed subset such that $L|_V$ is not big, then $V \subseteq Z$, hence $L^\perp = (L|_Z)^\perp$. On the other hand, Corollary 3.7 gives $\mathbf{B}_+(L) = \mathbf{B}_+(L|_Z)$, and we conclude that $\mathbf{B}_+(L) = L^\perp$. \square
