

Local & Global Errors : Stability

Want to solve

$$\begin{cases} y' = f(t, y) \\ y(t_0) = y_0 \end{cases}$$

Recall : multistep methods are of
the form

$$a_k w_n + a_{k-1} w_{n-1} + \dots + a_0 w_{n-k} = h [b_k f_n + b_{k-1} f_{n-1} + \dots + b_0 f_{n-k}] \quad (*)$$

$\hookrightarrow f(t_n, w_n)$

$b_k = 0 \Rightarrow$ explicit method

$b_k \neq 0 \Rightarrow$ implicit method (why?)

The multistep method (*) is said
to be convergent if

denoting by $w_n(h, t)$ the solution to
(*) we have

$$\lim_{h \rightarrow 0} w_n(h, t) = y(t)$$

true solution

for all $t \in [t_0, t_m]$ provided

$$\lim_{h \rightarrow 0} w(h, t_0 + nh) = w_0 \quad (0 \leq n \leq k)$$

and provided f satisfies the cond's $\underline{\text{of}}$

the Lipschitz theorem for exist. & uniqueness.

$$\Leftrightarrow \max_{n \in \{0, \dots, \frac{t_m - t_0}{h}\}} |w_n - y_n| \rightarrow 0 \quad \text{as } h \rightarrow 0$$

Stability and Consistency

Define the Polynomials (associated with $(*)$) \circ

$$P(z) = a_k z^k + a_{k-1} z^{k-1} + \dots + a_0$$

$$Q(z) = b_k z^k + b_{k-1} z^{k-1} + \dots + b_0$$

(small changes to initial cond'n
⇒ small changes to appx.)

We say the method is **stable** if all roots of P satisfy $|z| \leq 1$ (in the unit disk) and all roots with $|z|=1$ are simple (not repeated).

We say the method is **consistent** if $P(1)=0$ & $P'(1)=g(1)$

→ (difference eq'n → differential eq'n as $h \rightarrow 0$)

Theorem (Convergence)

(Method is stable & consistent)

↔ (Method is convergent)

Proof (See book for (\Leftarrow))

Example

Consider the milne method

$$x_n - x_{n-2} = h \left[\frac{1}{3} f_n + \frac{4}{3} f_{n-1} + \frac{1}{3} f_{n-2} \right]$$

Then $P(z) = z^2 - 1$

$$Q(z) = \frac{1}{3} z^2 + \frac{4}{3} z + \frac{1}{3}$$

$$P(z) = 0 \Rightarrow z = \pm 1 \quad (\text{simple roots})$$

so the method is stable

and since $P(1) = 0 \quad \& \quad P'(1) = Q(1)$
 $= 2$

$$\& \quad Q(1) = \frac{1}{3}(1)^2 + \frac{4}{3}(1) + \frac{1}{3} = 2 \\ = P(1)$$

then it is consistent, so

by the theorem it is convergent

More on Local Truncation Error

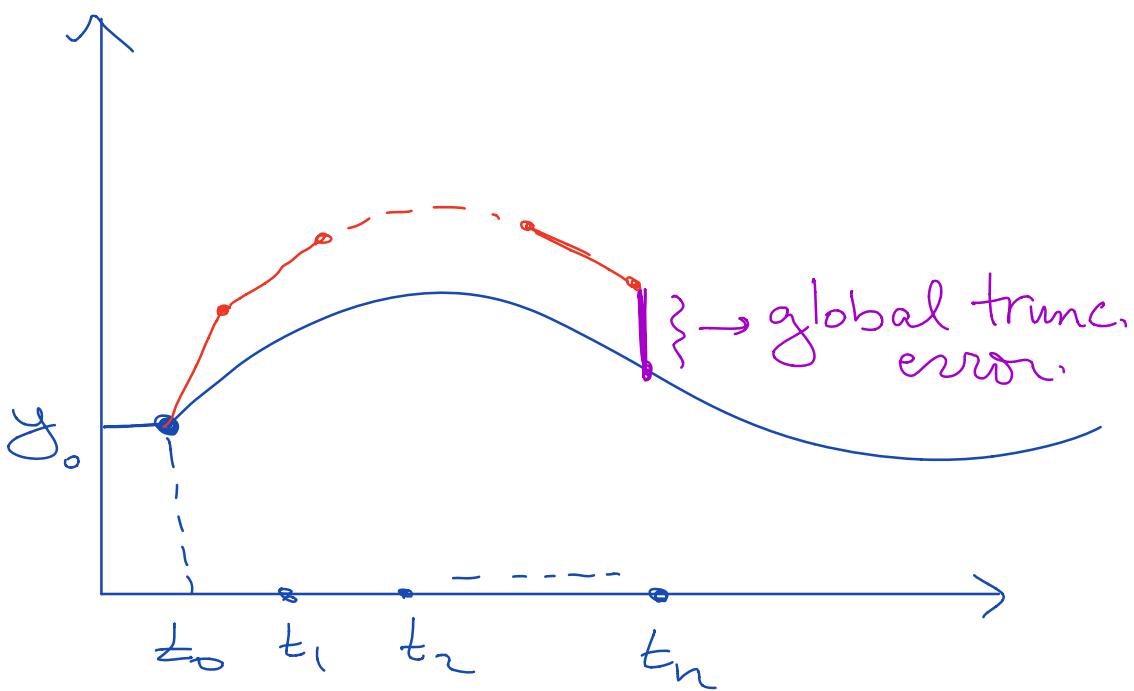

Recall: Local Truncation error
 $y(t_n)$

is $w_n - y^n$ assuming all previous estimates w_{n-1}, w_{n-2}, \dots are correct.

Theorem: For a multistep method (*) of order m if $y \in C^{m+2}$, and $\frac{\partial f}{\partial y}$ is cont $\$$

then

$$w_n - y(t_n) = O(h^{m+1})$$

Theorem :

Local Truncation error = $O(h^{m+1})$

\Rightarrow Global Truncation error
 $= O(h^m)$

Systems & higher order ODE's

Example : predator-prey models

$$\begin{cases} \dot{y}_1 = f_1(t, y_1, y_2) \\ \dot{y}_2 = f_2(t, y_1, y_2) \end{cases}$$

Given some initial conditions

$$y_1(t_0) = \alpha, y_2(t_0) = \beta$$

this becomes an IVP.

More generally:

$$\begin{cases} \dot{y}_1 = f_1(t, y_1, \dots, y_n) \\ \dot{y}_2 = f_2(t, y_1, \dots, y_n) \\ \vdots \\ \dot{y}_n = f_n(t, y_1, \dots, y_n) \end{cases}$$

We can write this in vector notation:

$$\left\{ \begin{array}{l} \dot{y}' = F(t, y) \xrightarrow{\in \mathbb{R}^n} \\ y(t_0) = y_0 \xrightarrow{\in \mathbb{R}^n} \end{array} \right.$$

↳ function $\mathbb{R}^{n+1} \rightarrow \mathbb{R}^n$

Fact : Can convert a higher order ODE to a system of first order ODE's

$$\Rightarrow y^{(n)} = f(t, y, y', \dots, y^{(n-1)})$$

$\uparrow \quad \uparrow \quad \uparrow$
 $x_1 \quad x_2 \quad x_n$

$$\Leftrightarrow \begin{cases} x_1' = x_2 \\ x_2' = x_3 \end{cases}$$

$$\begin{cases} x_n' = f(t, x_1, \dots, x_n) \end{cases}$$

Example: Convert the IVP below to a system of first-order ODE's with initial values

$$\left\{ \begin{array}{l} (\sin t)y''' + (\cos t y) + \sin(t^2 + y'') + (y')^3 \\ \quad = \log(t) \\ y(2) = 7 \\ y'(2) = 3, \quad y''(2) = -4 \end{array} \right.$$

Sol'n \circ Introduce $x_1, x_2, x_3 =$
 Let $x_1 = y$
 $x_2 = x_1'$
 $x_3 = x_2'$

$$\Rightarrow \begin{cases} x_1' = x_2 \\ x_2' = x_3 \\ x_3' = [\log t - x_2^3 - \sin(t^2 + x_3) - \cos(tx_1)] / \sin t \end{cases}$$

with $X(2) = (7, 3, -4)$

Example

Convert the system below into a system of first order ODE's

$$\begin{cases} (x')^2 + t e^{x_2} + y' = x' - x \\ y' y'' - \cos(x_1 y) + \sin(t x_2 y) = t \end{cases}$$

Sol'n : Let $x_1 = x, x_2 = x', x_3 = y, x_4 = y'$

$$\Rightarrow \begin{cases} x_1' = x_2 \\ x_2' = (x_2 - x_1 - t e^{x_3} - x_4)^{\frac{1}{2}} \\ x_3' = x_4 \\ x_4' = \frac{(x_1 + \cos(x_1 x_3) - \sin(t x_2 x_3))}{x_4} \end{cases}$$

So we've seen that higher order ODE's, and systems of higher order ODE's, can be rewritten as systems of 1st order ODE's. How do we solve them?

Solving systems of 1st order ODE's

- Taylor series method

We write a Taylor series approx. for each variable:

$$x_i(t+h) = x_i(t) + x'_i(t)h + \frac{x''_i(t)h^2}{2} + \dots + \frac{x_i^{(n)}(t)h^n}{n!} + \text{error}$$

⇒ In vector notation

$$\mathbf{X}(t+h) = \mathbf{X}(t) + \mathbf{X}'(t)h + \frac{\mathbf{X}''(t)h^2}{2} + \dots + \frac{\mathbf{X}^{(n)}(t)h^n}{n!} + \text{error}$$

Recall: one variable case \downarrow Taylor
method idea behind

$$y' = f(t, y)$$

$$\begin{aligned} y(t+h) &= y(t) + y'(t)h + \frac{y''(t)}{2!}h^2 \\ &\quad + \dots + \frac{y^{(m)}(t)}{m!}h^m + \text{error} \end{aligned}$$

$$\Rightarrow w_{n+1} = w_n + h \left[f_n + \underbrace{\frac{f'_n h}{2!} + \dots + \frac{f_n^{(m)} h^m}{m!}}_{\substack{\leftarrow \\ f(t_n, w_n)}} \right] \underbrace{\text{Chain rule!}}_{\substack{\{ \\ \text{Chain rule!}}}}$$

Same idea for systems!

Example:

$$\begin{cases} x' = x + y^2 - t^3 &=: f \\ y' = y + x^3 + \cos t &=: g \end{cases}$$

$$\begin{cases} x(1) = 3 \\ y(1) = 1 \end{cases}$$

Use $h=0.1$, and write the second order Taylor method

Sol'n: We'll need x', y' (\curvearrowright)
 x'', y''

$$\begin{aligned}x'' &= x' + 2yy' - 3t^2 =: f' \\y'' &= y' + 3x^2x' - \sin t =: g'\end{aligned}$$

Let w_n be the iterates associated with x & v_n be the iterates associated with y . Then with

$$t_0 = 1, h = 0.1, t_n = t_0 + nh$$

$$w_0 = 3$$

$$w_{n+1} = w_n + h \left[f_n + \frac{hf'_n}{2} \right]$$

$$v_{n+1} = v_n + h \left[g_n + \frac{hg'_n}{2} \right]$$

$$\text{where } f_n = w_n + v_n^2 - t_n^3$$

$$g_n = v_n + w_n^3 + \cos(t_n)$$

$$f'_n = f_n + 2v_n g_n - 3t_n^2$$

$$g'_n = g_n + 3w_n^2 f_n - \sin t_n$$

Other methods we studied
for first order IVP's can also
be generalized.

Example: RK4 to solve

$$X' = F(X)$$

Here $X = (x_0, x_1, \dots, x_n)^T$
 $\downarrow \quad \downarrow \quad \dots \quad \downarrow$
 $t \quad x_1 \quad \dots, x_n$

& the first eq'n is $x'_0 = 1$

$$X(t+h) = X(t) + \frac{1}{6}(F_1 + 2F_2 + 2F_3 + F_4)$$

with

$$\begin{cases} F = h F(X) \\ F_2 = h F\left(X + \frac{1}{2}F_1\right) \\ F_3 = h F\left(X + \frac{1}{2}F_2\right) \end{cases}$$

$$(F_1 = h F(X + F_3))$$

(Looks very similar to 1 variable case
but implementation requires
care).

- Multi-step methods
can also be generalized
similarly.
