Spectral and Stochastic Solutions to Boundary Value Problems on Magnetic Graphs

Sawyer Jack Robertson

University of Oklahoma

August 2, 2018
Abstract.
A magnetic graph is a graph $G$ equipped with a signature structure $\sigma$ on its edges. Magnetic graphs have been an important tool in the study of quantum mechanics since at least 1993, with the publication of a classic paper by Lieb and Loss. Among many other things, these graphs help us model simple electromagnetic systems. In this talk, we will explore the discrete magnetic Laplace operator $\mathcal{L}^\sigma_G$, a difference operator for complex-valued functions on the vertices of $G$. We will pose some discrete boundary value problems associated to this operator, and adapt two classic techniques to the setting of magnetic graphs to solve them. The first technique uses the spectral properties of the operator, and the second technique utilizes random walks adapted to this particular setting. Throughout, we will prove some useful results including a Green’s identity, mean value characterization of harmonic functions, and extensions of the solution techniques to Kronecker product graphs.
What is a magnetic graph?

- $G = (V(G), E(G))$ undirected, finite, no loops or multiple edges
- The **oriented edges** of $G$
  
  \[ E^{\text{or}}(G) := \{(u, v), (v, u) : \{u, v\} \in E(G)\}. \]

- A **signature** on $G$ is a map
  
  \[
  \sigma : E^{\text{or}}(G) \to S^1 : (u, v) \mapsto \sigma_{uv}
  \]

  s.t. $\sigma_{vu} = \overline{\sigma}_{uv}$.

- Gives notion of **direction** for the edges of $G$

- A **magnetic graph** is a pair $(G, \sigma)$.

Figure: Example graph with example signature taking real values, illustrated by edge coloring
What is a Discrete Laplace Operator?

- A general **weight function** on $G$ is some function $w_{uv}$ on $V(G) \times V(G)$, usually with some restrictions like positivity or symmetricity.

- A **discrete Laplace operator** associated to $w$ is a linear operator $L$ on the function space $\ell_2(V(G)) := \{ f : V(G) \to \mathbb{C} \}$ of the form

  \[
  (Lf)(u) = \sum_{v \in V(G)} w_{uv}(f(u) - f(v))
  \]  

- $w$ is chosen so that $L$ inherits properties of classical Laplace operator $\Delta$ for differentiable functions

- Wardetzky has studied the properties which a general discrete laplacian may inherit from the classical case, “no free lunch”

- The **combinatorial Laplacian** chooses $w_{uv} = 1 \iff u \sim v$, 0 otherwise. We build off of this.
Figure: A Cosine function on a 9 vertex path alongside its combinatorial Laplacian in green
The magnetic Laplace operator

- The **magnetic Laplace operator** extends (1) to a magnetic graph $(G, \sigma)$.
- Let $f \in \ell_2(V(G))$. Define $L_G$ by
  \[
  (L_G f)(u) = \sum_{v \sim u} f(u) - \sigma_{uv} f(v). \quad (2)
  \]

This operator is identified with a **Hermitian** matrix $L_G$. It is a **self-adjoint** operator.

- If $H \subsetneq V(G)$ is a subset of vertices, $L_H$ is its **magnetic Dirichlet Laplacian** and $\frac{\partial}{\partial \eta}$ is its **normal derivative** operator. These measure 'flow' of a function on $G$ into and out of $H$, resp.
- $\partial H$ is the **vertex boundary** of $H$, $\overline{H} := H \cup \partial H$.

Results (1), Identities

Theorem (Magnetic Mean Value Property)

A function $f \in \ell_2(V(G))$ is harmonic on a magnetic graph $(G, \sigma)$ if and only if at each vertex $u \in V(G)$, the following holds:

$$f(u) = \frac{1}{d_u^G} \left( \sum_{v \sim u \atop v \in G} \sigma_{uv} f(v) \right).$$

Theorem (Magnetic Green’s Identity)

Let $(G, \sigma), H$ be as before and $f, g \in \ell_2(V(H))$. Then the following holds:

$$\sum_{u \in H} (\mathcal{L}_H f)(u)g(u) - f(u)(\mathcal{L}_H g)(u) = \sum_{u \in \partial H} f(u) \frac{\partial g}{\partial \eta}(u) - \frac{\partial f}{\partial \eta}(u)g(u).$$
Results (2), Green’s Functions

Lemma

Let \((G, \sigma)\) be a connected magnetic graph, and suppose \(H \subsetneq V(G)\) is a proper subset of vertices which induces a connected subgraph in \(G\). Then \(L_H\) is an invertible matrix.

Theorem (Green's Function Formula)

Let \(G\) be a finite connected graph without loops or multiple edges, and let \(H \subsetneq V(G)\) be a proper subset of \(k\) vertices which is assumed to induce a connected subgraph. Let \(\{e_i\}_{i=1}^{m}\) be an orthonormal basis of \(\ell_2(H)\) of eigenvectors of \(L_H\) associated to eigenvalues \(\{\lambda_i\}_{i=1}^{m}\) counted with multiplicity. Let \(L_H^{-1}\) be interpreted as a function on \(H \times H\). We have the following

\[
L_H^{-1}(i, j) = \sum_{k=1}^{m} \frac{1}{\lambda_k} e_k(i) e_k(j)
\]

where \((i, j) \in H \times H\) (we use slightly different notation for vertices in \(H\) here to be consistent with the \(\{e_i\}\) notation).
Results (3), Poisson Problem

**Magnetic Poisson Problem** Let $f \in \ell_2(H)$ and $g \in \ell_2(\partial H)$ be given functions. We wish to find a function $\Psi \in \ell_2(H)$ for which

$$\begin{align*}
(L_G \Psi)(u) &= f(u) \quad u \in H \\
\Psi(u) &= g(u) \quad u \in \partial H
\end{align*}$$

We shall solve this problem using a **spectral theoretic solution**, whose combinatorial origins are due to Chung.

**Theorem (Spectral Theoretic Solution)**

Let $\{e_i\}_{1 \leq i \leq k}$ be an orthonormal basis of $\ell_2(H)$ of eigenvectors for $L_H$, associated to real eigenvalues $\{\lambda_i\}_{1 \leq i \leq k}$, counted with multiplicity. Extend this system on $H$ to a family $\{\tilde{e}_i\}$ on $\overline{H}$ by setting $\tilde{e}_i \equiv 0$ on $\partial H$. The unique solution to (3) may be explicitly given by

$$\Psi(w) = \begin{cases} 
(L_H^{-1} f)(w) - \sum_{i=1}^{m} \frac{e_i(w)}{\lambda_i} \left[ \sum_{u \in \partial H} \frac{\partial \tilde{e}_i}{\partial \eta}(u) g(u) \right] & w \in H \\
g(w) & w \in \partial H
\end{cases}$$
The magnetic **Dirichlet problem** is stated as follows: Let \((G, \sigma)\) be a **simple** and **connected** magnetic graph and let \(H\) be a proper subset in \(V(G)\) which induces a connected subgraph. Let \(f \in \ell_2(\partial H)\) be a given boundary condition. We wish to find a function \(\Psi \in \ell_2(\overline{H})\) for which

\[
\begin{align*}
(L_G \Psi)(u) &= 0 & u &\in H \\
\Psi(u) &= f(u) & u &\in \partial H.
\end{align*}
\] (4)

**Theorem (Dirichlet Solution 1)**

Let \(G, H, f, \Psi\) be as in (4). Let \(S_t\) be a random walk with associated initial distribution \(\mu_0\). The unique solution to (4) may be given by

\[
\Psi(u) = \mathbb{E}[f(\tilde{S}_T) \prod_{i=1}^T \sigma_{S_{i-1}S_i} : \mu_0 = \delta_u], \quad u \in \overline{H}
\] (5)

where \(\tilde{S}_t\) is the modified random walk which stops once reaching the boundary at step \(T\).
Magnetic Lifts

Let \((G, \sigma)\) be a magnetic graph. Further assume that \(\sigma\) takes values strictly in \(S_p^1\) for some integer \(p \geq 2\). Write \(S_p^1 = \{\omega_i\}_{i=0}^{p-1}\). We define the lift of \(G\) to be the non-magnetic graph \(\hat{G}\) consisting of vertex set \(G \times S_p^1\) and edges defined by

\[
(u, \omega_i) \sim (v, \omega_j) \text{ in } \hat{G} \iff u \sim v \text{ in } G \text{ and } \omega_j = \omega_i \sigma_{uv}.
\]

The subsets \(G \times \{\omega_i\} \subseteq V(\hat{G})\) for each fixed \(\omega_i \in S_p^1\) are called the levels of the magnetic lift.

Current research questions concern deducing properties of \(\hat{G}\) determined by properties of \(G\) and \(\sigma\).
Magnetic Lifts (Illustration)

**Figure:** A grid graph, with signature 1 on the blue edges and signature -1 on the dotted red edges.

**Figure:** The magnetic lift associated to the graph on the left; visualized in three dimensions to emphasize the 'level' structures.
Theorem

Let $G, H, f, \Psi$ be as in (4). Assume further that $\sigma$ takes values in some $S_p^1 = \{\omega_i\}_{i=0}^{p-1}$ for $p \geq 2$ and that the lift $\hat{G}$ is connected and not bipartite. Let $S_t$ be a random walk on $\hat{G}$ on vertices of the form $S_t = (u_t, \sigma_t)$, with associated initial distribution $\mu_0$ on the lift $\hat{G}$. The unique solution to (4) may be given by

$$
\Psi(u) = \mathbb{E}[f(\tilde{u}_T)\sigma_T : \mu_0 = \delta_{(u,\omega_0)}], \quad u \in \overline{H}
$$

(6)

where $\tilde{S}_t$ is the modified random walk process formulated in the previous slide.
Open Questions & Acknowledgements

- Which solution technique can be considered more 'efficient' in the computational sense?
- In what way(s) do magnetic lifts simplify the problem, if at all?
- How can we teach these techniques to a computer and implement them on a larger scale?
- I would like to greatly thank my research advisor at the University of Oklahoma Prof. Javier Alejandro Chávez Domínguez.
- I would also like to thank the MathFest organizers for having me (and paying the bills!), as well as my parents.
- I would like to acknowledge the University of Oklahoma Foundation for supporting this research indirectly through scholarship contributions to the author.
