Homotopy Methods for Counting Reaction Network Equilibria

G. Craciun, J. W. Helton, R. J. Williams

http://www.math.ucsd.edu/~williams/reactionnet/chw.pdf
Dynamical System Models

DS models of chemical reaction networks have form

\[ \dot{c} = f(c) \]  \hspace{1cm} (1)

where \( f \) is a smooth \( \mathbb{R}^n \)-valued function defined on a subset of \( \mathbb{R}^n_{\geq 0} \).

Typically such DS are high-dimensional, nonlinear, and parameters defining \( f \) are not well known.

Focus here on positive equilibria for (1), i.e., on \( c^* \in \mathbb{R}^n_{>0} \) for which \( f(c^*) = 0 \).
Some References

Positive Equilibria for Chemical Reaction Networks

Sufficient Conditions for Uniqueness of Positive Equilibria for All Values of Model Parameters: Recent work of Craciun, Feinberg et al. using graph-theoretical methods (assumes mass-action kinetics).

Examples of Reaction Networks Admitting Multiple Positive Equilibria for Some Values of the Parameters: Recent work of Craciun, Feinberg et al. with mass-action kinetics.

Here we describe methods based on homotopy invariance of degree for determining how the number of positive equilibria for a chemical reaction network depends on the parameters of the model.
Key Condition

The determinant of the Jacobian $\frac{\partial f}{\partial c}(\cdot)$ of $f$ is either strictly positive or strictly negative everywhere on its domain of definition.

(Craciun and Feinberg et al. consider situations where this holds for all values of the rate constants.)

(Note: Under this condition, the absolute value of the topological degree of $f$ counts the number of zeros of $f$.)
Advantages of Homotopy Method

- Don’t need conditions for all rate constants
- Can obtain existence of positive equilibria
- Kinetics can be more general than mass-action
OUTLINE

• Consequence of Homotopy Invariance of Degree

• Example: Bounded State Space, Not Mass Action

• Application to a Conservative Reaction Network with Inflows and Outflows (CFSTR)

• Examples: Mass Action
Consequence of Homotopy Invariance of Degree

For a bounded domain $\Omega \subset \mathbb{R}^n_{>0}$, consider
\[ \dot{c} = f_\lambda(c), \quad c \in \Omega, \]

where $f_\lambda : \overline{\Omega} \rightarrow \mathbb{R}^n$ for $\lambda \in [0, 1]$ is a continuously varying family of smooth functions.

Suppose that

(i) $f_\lambda$ does not have any zeros on $\partial \Omega$ for all $\lambda \in [0, 1]$,

(ii) $\det \left( \frac{\partial f_\lambda}{\partial c}(c) \right) \neq 0$ for all $c \in \Omega$, for $\lambda = 0, 1$.

Then the number of zeros of $f_0$ in $\Omega$ equals the number of zeros of $f_1$ in $\Omega$. 
Example of Arcak and Sontag  
(not mass action)

Simplified model of mitogen activated protein kinase (MAPK) cascades with inhibitory feedback:

\[
\begin{align*}
\dot{c}_1 &= -\frac{b_1 c_1}{c_1 + a_1} + \frac{d_1 (1 - c_1)}{e_1 + (1 - c_1)} \frac{\mu}{1 + kc_3} \\
\dot{c}_2 &= -\frac{b_2 c_2}{c_2 + a_2} + \frac{d_2 (1 - c_2)}{e_2 + (1 - c_2)} c_1 \\
\dot{c}_3 &= -\frac{b_3 c_3}{c_3 + a_3} + \frac{d_3 (1 - c_3)}{e_3 + (1 - c_3)} c_2.
\end{align*}
\]

The variables \(c_j \in [0, 1], \ j = 1, 2, 3\) denote the (normalized) concentrations of the active forms of the proteins.

*Confirm result of AS that there is a unique positive equilibrium for any choice of the strictly positive parameters, \(a_1, a_2, a_3, b_1, d_1, e_1, b_2, d_2, e_2, b_3, d_3, e_3, \mu, k\).*
Continuous Flow Stirred Tank Reactor

Conservative dynamical system augmented with inflows and outflows:

\[
\dot{c} = f(c) := c_{in} - c + g(c)
\]  \hspace{1cm} (2)

where \(c_{in} \in \mathbb{R}^n_>0\), and the function \(g : \mathbb{R}^n_0 \rightarrow \mathbb{R}^n\) is a species formation rate function for a conservative chemical reaction network:

\[
g(c) = Sr(c) \quad \text{for} \quad c \in \mathbb{R}^n_{\geq 0}.
\]

In particular, \(g\) is assumed to be a smooth function such that

(i) for each \(j \in \{1, \ldots, n\}\), \(g_j(c) \geq 0\) whenever \(c_j = 0\) (positive invariance),

(ii) there is \(m \in \mathbb{R}^n_{>0}\) such that \(m \cdot g(c) = 0\) for all \(c \in \mathbb{R}^n_{\geq 0}\) (mass conservation).
Theorem

The augmented dynamical system

\[ \dot{c} = f(c) := c_{in} - c + g(c) \]

has no equilibria on the boundary of \( \mathbb{R}^n_{\geq 0} \). Furthermore, if

\[ \det \left( \frac{\partial f}{\partial c} \right) \neq 0 \quad \text{on } \mathbb{R}^n_{>0}, \]

then there is exactly one equilibrium point in \( \mathbb{R}^n_{>0} \).
Example

Consider the chemical reaction network

\[
\begin{align*}
A + B & \rightarrow P \\
B + C & \rightarrow Q \\
C & \rightarrow 2A
\end{align*}
\]

Associated DS for mass-action kinetics (augmented with inflows and outflows):

\[
\begin{align*}
\dot{c}_A &= k_{0\rightarrow A} - k_{A\rightarrow 0} c_A - k_{A+B\rightarrow P} c_A c_B + 2k_{C\rightarrow 2A} c_C \\
\dot{c}_B &= k_{0\rightarrow B} - k_{B\rightarrow 0} c_B - k_{A+B\rightarrow P} c_A c_B - k_{B+C\rightarrow Q} c_B c_C \\
\dot{c}_C &= k_{0\rightarrow C} - k_{C\rightarrow 0} c_C - k_{B+C\rightarrow Q} c_B c_C - k_{C\rightarrow 2A} c_C \\
\dot{c}_P &= k_{0\rightarrow P} - k_{P\rightarrow 0} c_P + k_{A+B\rightarrow P} c_A c_B \\
\dot{c}_Q &= k_{0\rightarrow Q} - k_{Q\rightarrow 0} c_Q + k_{B+C\rightarrow Q} c_B c_C.
\end{align*}
\]

By work of Craciun and Feinberg, the dynamical system has multiple positive equilibria for some values of the reaction rate parameters.
Example (cont.)

For simplicity, assume outflow rates $k_{A \rightarrow 0}, \ldots, k_{Q \rightarrow 0}$ are all equal to 1. The determinant of the Jacobian of the reaction rate function has the following expansion:

$$
\det(\partial f/\partial c) = -1 - k_{A+B \rightarrow PC_A} - k_{B+C \rightarrow QC_C} \\
- k_{B+C \rightarrow QC_B} \\
- k_{B+C \rightarrow Q} k_{A+B \rightarrow PC_A} c_B - k_{C \rightarrow 2A} \\
- k_{C \rightarrow 2A} k_{A+B \rightarrow PC_A} \\
- k_{C \rightarrow 2A} k_{B+C \rightarrow QC_C} - k_{A+B \rightarrow PC_B} \\
- k_{A+B \rightarrow P} k_{C \rightarrow 2AC_B} \\
- k_{A+B \rightarrow P} k_{B+C \rightarrow QC_B^2} \\
- k_{A+B \rightarrow P} k_{B+C \rightarrow QC_B c_C} \\
+ k_{A+B \rightarrow P} k_{B+C \rightarrow QC_C} k_{C \rightarrow 2AC_B c_C}.
$$

There is only one (anomalous sign) in the determinant expansion (with monomial $c_B c_C$).
Example (cont.)

Combining all terms with this monomial gives

\[- k_{A+B \rightarrow P^k B + C \rightarrow Q} + k_{A+B \rightarrow P^k B + C \rightarrow Q^k C \rightarrow 2A} c_B c_C.\]

If \( k_{C \rightarrow 2A} \leq 1 \), then \( \det(\partial f/\partial c) < 0 \) for this network, everywhere on \( \mathbb{R}^5_0 \).

The reaction network before augmentation with inflows and outflows satisfies positive invariance and the vector \((m_A, m_B, m_C, m_P, m_Q) = (1, 1, 2, 2, 3)\) is a conserved mass vector.

Hence, the dynamical system, augmented with inflows and unit rate outflows, has a unique positive equilibrium for all positive values of the reaction rates such that \( k_{C \rightarrow 2A} \leq 1 \).
Some Further Examples of Craciun & Feinberg
