Continuous Time Markov Chains

Def (Discrete-time Markov chain)

Let $(X_n)_{n \geq 0}$ be a discrete time stochastic process taking values in $\mathbb{Z}_+ = \{0, 1, 2, \dots\}$ (for convenience). $(X_n)_{n \geq 0}$ is called Markov chain if for any $n \in \mathbb{N}$ and $i_0, i_1, \dots, i_{n-1}, i, j \in \mathbb{Z}_+$

$$P(X_{n+1} = j \mid X_0 = i_0, X_1 = i_1, \dots, X_{n-1} = i_{n-1}, X_n = i) = P(X_{n+1} = j \mid X_n = i)$$

Def (Continuous-time Markov chain)

Let $(X_t)_{t \geq 0} = (X_t : 0 \leq t < \infty)$ be a continuous time process taking values in \mathbb{Z}_+ . $(X_t)_{t \geq 0}$ is called Markov chain if for any $n \in \mathbb{N}$, $0 \leq t_0 < t_1 < \dots < t_{n-1} < s, t > 0$, $i_0, i_1, \dots, i_{n-1}, i, j \in \mathbb{Z}_+$

$$P(X_{s+t} = j \mid X_{t_0} = i_0, X_{t_1} = i_1, \dots, X_{t_{n-1}} = i_{n-1}, X_s = i) \stackrel{(*)}{=} P(X_{s+t} = j \mid X_s = i)$$

Transition probability function

One way of describing a continuous time MC is by using the transition probability functions.

Def. Let $(X_t)_{t \geq 0}$ be a MC. We call

$$P(X_{s+t} = j \mid X_s = i), \quad i, j \in \{0, 1, \dots\}, \quad s \geq 0, \quad t > 0$$

the transition probability function for $(X_t)_{t \geq 0}$.

If $P(X_{s+t} = j \mid X_s = i)$ does not depend on s , we say that $(X_t)_{t \geq 0}$ has stationary transition probabilities and we define $P_{ij}(t) := P(X_{s+t} = j \mid X_s = i) (= P(X_t = j \mid X_0 = i))$

[compare with n -step transition probabilities]

Characterization of the Poisson process

Experiment: count events occurring along $[0, +\infty)$ } or 1-D space
time

Denote by $N((a, b])$ the number of events that occur on $(a, b]$.

Assumptions:

1. Number of events happening in disjoint intervals are independent.
2. For any $t \geq 0$ and $h > 0$, the distribution of $N((t, t+h])$ does not depend on t (only on h , the length of the interval)
3. There exists $\lambda > 0$ s.t. $P(N((t, t+h]) \geq 1) = \lambda h + o(h)$ as $h \rightarrow 0$
(rare events)
4. Simultaneous events are not possible: $P(N((t, t+h]) \geq 2) = o(h), h \rightarrow 0$

$$f(h) = o(h) \quad \text{if} \quad \lim_{h \rightarrow 0} \frac{f(h)}{h} = 0$$

Transition probabilities of the Poisson process

Let $(X_t)_{t \geq 0}$ be the Poisson process.

Define the transition probability functions

$$P_{ij}(h) := P(X_{t+h} = j \mid X_t = i), \quad i, j \in \{0, 1, 2, \dots\}, \quad t \geq 0, \quad h > 0$$

What are the infinitesimal (small h) transition probability functions for $(X_t)_{t \geq 0}$? As $h \rightarrow 0$,

$$\begin{aligned} P_{ii}(h) &= P(X_{t+h} = i \mid X_t = i) \stackrel{!}{=} \\ &= P(X_{t+h} - X_t = 0 \mid X_t = i) = P(X_{t+h} - X_t = 0) = 1 - \lambda h + o(h) \end{aligned}$$

$$P_{i,i+1}(h) = P(X_{t+h} = i+1 \mid X_t = i) = P(X_{t+h} - X_t = 1) = \lambda h + o(h)$$

$$\sum_{j \neq \{i, i+1\}} P_{ij}(h) = o(h)$$

Poisson process and transition probabilities

To sum up: $(X_t)_{t \geq 0}$ is a MC with (infinitesimal) transition probabilities satisfying

$$P_{ii}(h) = 1 - \lambda h + o(h)$$

$$P_{i,i+1}(h) = \lambda h + o(h)$$

$$\sum_{j \notin \{i, i+1\}} P_{ij}(h) = o(h)$$

What if we allow $P_{ij}(h)$ depend on i ?

↳ birth and death processes

Pure birth processes

Def Let $(\lambda_k)_{k \geq 0}$ be a sequence of positive numbers.

We define a pure birth process as a Markov process

$(X_t)_{t \geq 0}$ whose stationary transition probabilities satisfy

$$1. P_{k, k+1}(h) = \lambda_k h + o(h)$$

$$2. P_{k, k}(h) = 1 - \lambda_k h + o(h) \quad \text{as } h \rightarrow 0$$

$$3. P_{k, j}(h) = 0 \quad \text{for } j < k$$

$$4. X_0 = 0$$

Related model. Yule process: $\lambda_k = \beta k$ for some $\beta > 0$.

Describes the growth of a population

- birth rate is proportional to the size of the population

Birth processes and related differential equations

Now define $P_n(t) = P(X_t = n)$. For small $h > 0$

$$P_n(t+h) = P(X_{t+h} = n) = \sum_{k=0}^n P(X_{t+h} = n \mid X_t = k) P(X_t = k)$$

$$= \sum_{k=0}^n P_{kn}(h) P_k(t)$$

$$= P_{n,n}(h) P_n(t) + P_{n-1,n}(h) P_{n-1}(t) + \sum_{k=0}^{n-2} P_{k,n}(h) P_k(t)$$

$$= (1 - \lambda_n h) P_n(t) + \lambda_{n-1} h P_{n-1}(t) + o(h)$$

$$= P_n(t) - \lambda_n h P_n(t) + \lambda_{n-1} h P_{n-1}(t) + o(h)$$

$$P_n(t+h) - P_n(t) = -\lambda_n h P_n(t) + \lambda_{n-1} h P_{n-1}(t) + o(h)$$

$$P_n'(t) = \lim_{h \rightarrow 0} \frac{P_n(t+h) - P_n(t)}{h} = -\lambda_n P_n(t) + \lambda_{n-1} P_{n-1}(t)$$

Birth processes and related differential equations

$P_n(t)$ satisfies the following system

of differential eqs.

with initial conditions

$$(*) \begin{cases} P_0'(t) = -\lambda_0 P_0(t) \\ P_1'(t) = -\lambda_1 P_1(t) + \lambda_0 P_0(t) \\ P_2'(t) = -\lambda_2 P_2(t) + \lambda_1 P_1(t) \\ \vdots \\ P_n'(t) = -\lambda_n P_n(t) + \lambda_{n-1} P_{n-1}(t) \\ \vdots \end{cases} \quad \begin{cases} P_0(0) = 1 \\ P_1(0) = 0 = \mathbb{P}(X_0=1) \\ P_2(0) = 0 = \mathbb{P}(X_0=2) \\ \vdots \\ P_n(0) = 0 \\ \vdots \end{cases}$$

Solving this system gives the p.m.f. of X_t for any t

$$P(X_t = k) = P_k(t)$$
